SKF – the knowledge engineering company

From one simple but inspired solution to a misalignment problem in a textile mill in Sweden, and fifteen employees in 1907, SKF has grown to become a global industrial knowledge leader.

Over the years, we have built on our expertise in bearings, extending it to seals, mechatronics, services and lubrication systems. Our knowledge network includes 46 000 employees, 15 000 distributor partners, offices in more than 130 countries, and a growing number of SKF Solution Factory sites around the world.

Research and development

We have hands-on experience in over forty industries based on our employees' knowledge of real life conditions. In addition, our world-leading experts and university partners pioneer advanced theoretical research and development in areas including tribology, condition monitoring, asset management and bearing life theory. Our ongoing commitment to research and development helps us keep our customers at the forefront of their industries.

Meeting the toughest challenges

Our network of knowledge and experience, along with our understanding of how our core technologies can be combined, helps us create innovative solutions that meet the toughest of challenges. We work closely with our customers throughout the asset life cycle, helping them to profitably and responsibly grow their businesses.

Working for a sustainable future

Since 2005, SKF has worked to reduce the negative environmental impact from our operations and those of our suppliers. Our continuing technology development resulted in the introduction of the SKF BeyondZero portfolio of products and services which improve efficiency and reduce energy losses, as well as enable new technologies harnessing wind, solar and ocean power. This combined approach helps reduce the environmental impact both in our operations and our customers' operations.

SKF Solution Factory makes SKF knowledge and manufacturing expertise available locally to provide unique solutions and services to our customers.

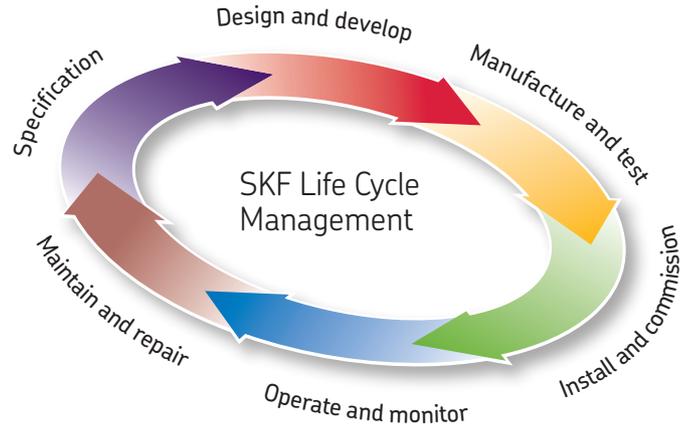

Working with SKF IT and logistics systems and application experts, SKF Authorized Distributors deliver a valuable mix of product and application knowledge to customers worldwide.

Our knowledge – your success

SKF Life Cycle Management is how we combine our technology platforms and advanced services, and apply them at each stage of the asset life cycle, to help our customers to be more successful, sustainable and profitable.

Working closely with you

Our objective is to help our customers improve productivity, minimize maintenance, achieve higher energy and resource efficiency, and optimize designs for long service life and reliability.

Bearings

SKF is the world leader in the design, development and manufacture of high performance rolling bearings, plain bearings, bearing units and housings.

Innovative solutions

Whether the application is linear or rotary or a combination, SKF engineers can work with you at each stage of the asset life cycle to improve machine performance by looking at the entire application. This approach doesn't just focus on individual components like bearings or seals. It looks at the whole application to see how each component interacts with each other.

Machinery maintenance

Condition monitoring technologies and maintenance services from SKF can help minimize unplanned downtime, improve operational efficiency and reduce maintenance costs.

Design optimization and verification

SKF can work with you to optimize current or new designs with proprietary 3-D modelling software that can also be used as a virtual test rig to confirm the integrity of the design.

Sealing solutions

SKF offers standard seals and custom engineered sealing solutions to increase uptime, improve machine reliability, reduce friction and power losses, and extend lubricant life.

Mechatronics

SKF fly-by-wire systems for aircraft and drive-by-wire systems for off-road, agricultural and forklift applications replace heavy, grease or oil consuming mechanical and hydraulic systems.

Lubrication solutions

From specialized lubricants to state-of-the-art lubrication systems and lubrication management services, lubrication solutions from SKF can help to reduce lubrication related downtime and lubricant consumption.

Actuation and motion control

With a wide assortment of products – from actuators and ball screws to profile rail guides – SKF can work with you to solve your most pressing linear system challenges.

Preferred range

The SKF preferred range encompasses the most frequently used sizes of planetary roller screws and recirculating roller screws. Within that assortment, standard size nuts are stocked at SKF factories in Europe and North America for improved availability, greater value, and shorter delivery times. Shafts are manufactured according to customer requirements.

Design and manufacturing operations

- Standard roller screws with standard load ratings are available with axial play (SR or SV prefix), or without backlash (BR or BV prefix)
- Nut dimensions are detailed hereafter
- Standard shaft end machining can include turning, milling and grinding operations
- End machining is available for SKF support bearings

Materials

- For the preferred range, shafts and nuts are manufactured with standard high quality roller screw steel, detailed in the present SKF catalogue *Roller screws*
- Stainless steel and special treatments are not available with the preferred range

Capabilities

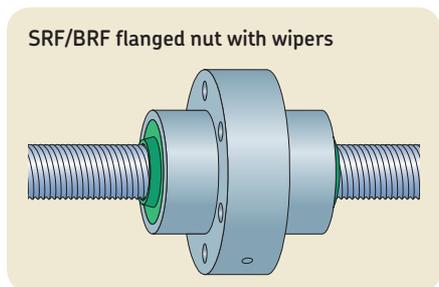

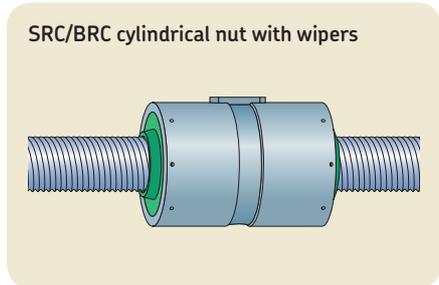

- Machining operations such as splines, hollow shaft, etc. are possible, but might require more time to complete
- Unless specified, manufacturing tolerances will be according to ISO 3408–3 class 5
- Lead precision is G5 according to ISO standards. G3 and G1 also possible on request
- Screw assemblies are shipped with a protective rust inhibitor coating
- Special documents can be supplied on request: Certificate of conformity to customer drawings # 1969981, lead precision curve
- Matching FLRBU support bearings size 2 to 6 can be delivered with the screws

Export note

- Product for nuclear, aerospace or military applications may be subject to export restrictions and/or licensing requirements. In such cases, delivery time shall be dependent upon securing approvals from the appropriate governmental authority.

Planetary roller screws with standard nuts in stock

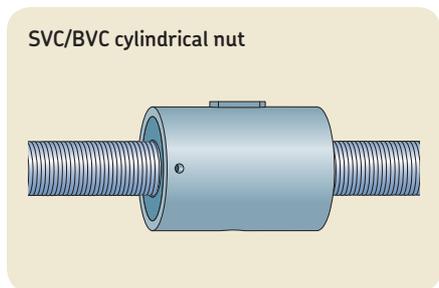

- SRC cylindrical nut with axial play
- BRC cylindrical nut without backlash
- SRF flanged nut with axial play
- BRF flanged nut without backlash
- SRC/BRC/SRF/BRF nuts with wiper recesses as standard
- Standard wipers supplied on request

Nominal diameter	Lead (right hand)	Basic load rating SRC/BRC nut		SRF/BRF nut		Maximum total shaft length L_{tp}

Recirculating roller screws with standard nuts in stock

- SVC cylindrical nut with axial play
- BVC cylindrical nut without backlash
- SVC/BVC nuts without wiper recess, no wiper availability

Nominal diameter	Lead (right hand)	Basic load rating SVC/BVC nut		Maximum total shaft length L_{tp}
		C_a	C_{0a}	
mm		kN		mm
20	1	18,5	36,6	1 300
25	1	32,9	68,4	1 650
32	1	64,3	159	2 150

Introduction to roller screws

SKF roller screws, high performance driving solutions

A wide assortment of industries rely on SKF roller screws for their actuation requirements. Leading the trend to move from traditional forms of linear actuation, SKF roller screws represent the state of the art driving force for powerful electro-mechanical actuation.

SKF is a pioneer in the technology of roller screws and offers high quality, high performance and the widest assortment of roller screws available on the market.

The SKF in-house highly integrated manufacturing process uses the latest machining technology including soft and hard machining, heat treatment (induction and through hardening), grinding and assembly operations. SKF manufacturing facilities also house laboratories dedicated to life tests, tribology, noise measurement and metallurgy. Beyond the standard assortment made from high grade bearing steel, SKF offers special variants with stainless steel and high temperature steel combined with coatings, etc. to respond to the most demanding applications.

SKF offers three main variants of planetary roller screws that do not require roller recirculation:

- The traditional SR assortment with threaded rollers synchronized to the nut, thanks to identical helix angle for the rollers and the nut
- The HR Ultra Power roller screws with increased capabilities compared to the SR assortment
- The ISR inverted roller screws with threaded rollers synchronized to the screw shaft, thanks to identical helix angle for the rollers and the shaft.

In addition, SKF offers special variants of planetary roller screws:

- The SRR rotating nut roller screws
- Zero lead roller screws that can advantageously replace a traditional thrust bearing solution when extreme axial load carrying capacity, low weight and compactness are required.

SKF offers a wide assortment of recirculating roller screws. Since the rollers are circumferentially grooved, after each complete revolution around the nut, the grooved rollers must be recirculated back to their starting point on one side of the nut, with the help of cams and axial groove inside the nut.

Small leads are possible with a relatively larger thread pitch on the shaft and nut. This feature offers the ideal combination of small lead, high load carrying capacity, a high degree of stiffness and precision.

Nevertheless, the recirculating roller screws present lower speed and acceleration capabilities than planetary roller screws.

Planetary roller screws SR

- Wide assortment of diameters and leads for numerous applications
- Reliable driving solution with high loads and speeds capabilities

Ultra Power planetary roller screws HR

- Extreme load carrying capacity
- Robustness and long service life for highly demanding applications

Inverted planetary roller screws ISR

- All the features and benefits of the planetary roller screw design
- Plus small leads, high load carrying capacity within a compact design

Rotating nut planetary roller screws SRR

- Operation similar to electro-mechanical cylinders
- Compact, integrated support bearing and roller screw nut functions

Zero lead roller screws

- Thrust bearing solution for special applications
- High thrust carrying capacity with compactness

Recirculating roller screws SV

- Small leads associated with high load carrying capacity
- Fine resolution and stiffness for ultra precision applications

Expectations with electro-mechanical actuation

Increased productivity for industrial grade applications with operational duty cycle over 70%

Up to 70% energy savings compared to hydraulic and pneumatic actuation technologies

Functionality, flexibility and controllability

Reliability

Higher repeatability and process stability

Easy integration into work cells and existing systems

Higher degree of precision

Low noise levels

Cleanliness

Lower total cost of ownership (TCO) compared to traditional types of actuation

SKF roller screw solutions

High load carrying capacity and cycling capability
Accommodate high accelerations and high speeds

Mechanical efficiency usually greater than 80%

Widest assortment of roller screws available on the market
Accommodate heavy loads with transportation applications
Provide accuracy for positioning applications
Custom designs and flexible manufacturing equipment

By design, the planetary roller screw offers greater reliability than other driving solutions

Limited wear, in particular for screws that have been run in at the factory

High power density

High degree of positioning accuracy further increased without backlash or with preload
Recirculating roller screws with small leads are recommended for ultra-precision applications

Very smooth and quiet operation with planetary roller screws

Roller screws consume a very small amount of lubricants

Long service life and reliability

Typical applications for roller screws

Application examples

Plastic moulding

Injection moulding, blow moulding, thermo-forming

Broaching

Automotive and aircraft industries

Electro-mechanical press

Top slide and die cushion for forming press
Punching press

Factory automation

Gluing, riveting, welding, clinching, joining, bending, clamping, etc.

Oil & gas industry

Surface and subsea valves, downhole tools, offshore equipment

Why SKF customers choose roller screw technology

Improved machine productivity, energy savings, cleanliness.

Smooth continuous cutting operation.
A high degree of stiffness provides a better surface finish for the part.

Dynamic load rating up to 4 000 kN, the force of hydraulic actuation, the speed of pneumatic actuation.

Accurate and repeatable, faster resetting, energy savings, reduced downtime, cleanliness, compactness.

Robust, compact, high power density and high temperature rating.

Application examples

Aerospace

Aileron, flap, slat, landing gear, wheel steering, ram air door, thrust reverser

Railway

Titling actuators, active suspension

Steel industry

Tundish car, ladle turret, continuous casting

Space and telescope

Optical focus, mirror shape control, solar arrays release

Simulator

Flight simulator, wave simulator, engineering test benches, entertainment equipment

Why SKF customers choose roller screw technology

Efficiency, reliability, weight saving, compact.

Reliability, robustness, low maintenance.

High power density, high degree of reliability in extremely harsh environments.

High resolution, precision and stiffness.

High speeds and accelerations, fast and accurate positioning and response.

Roller screws conceptual design advantage over ball screws

With planetary roller screws, the application load is transmitted from the nut to the shaft through the barrel-shaped surfaces of the rollers. The number of contacts and the total surface area of the contacts between the shaft, the rollers and the nut are substantially increased compared to the ball screw design, resulting in larger dynamic and static load carrying capacities (→ fig. 1).

The absence of recirculating element embodies the fundamental conceptual advantage of the planetary roller screws. This feature eliminates the main failure mode of ball screws, that is linked to the recirculation of the balls. Indeed, recirculating heavily loaded balls induces alternate stresses on the balls and shock loads arising from the change of trajectory.

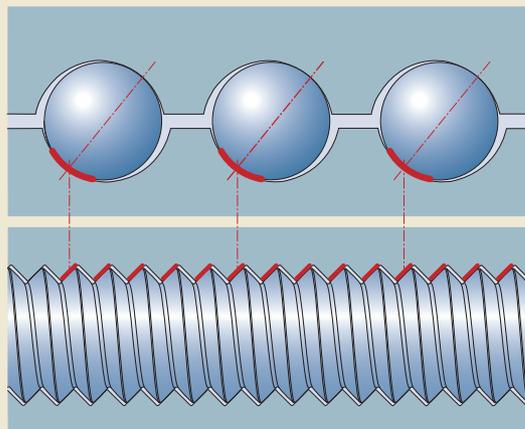

In addition, satellite rollers never come into contact with each other. This is a significant advantage of this product over most ball screw designs. Balls come into contact with each other in most ball screw designs, generating friction and adding a potential failure mode to the ball screw concept.

With recirculating roller screws, the application load transfers from the shaft to the nut through a set of grooved rollers. This design permits very small leads while offering high load carrying capacity and axial stiffness. This mechanical advantage minimizes input torque and increases application resolution and performance. They can simplify a complete transmission and improve its rigidity. They are often used in applications involving advancing technology where reliable optimum performance is essential.

Roller screw concept	Advantages over a ball screw	User benefits
Large number of contact points	High load carrying capacity and up to 10 times longer service life	Lower total cost of ownership (TCO)
Satellite rollers	Roller screw rotational speeds up to 50% higher than a ball screw with similar carrying capacity Roller screw acceleration up to 3 times higher Absence of recirculation eliminating a significant failure mode	Increased speed of operations Higher productivity Higher degree of reliability
Planetary roller screws with small lead (down to 2,00 mm)	High load carrying capacity compared to ball screws with small lead which are designed with small diameter balls which have low load carrying capacity	High load carrying capacity combined with positioning accuracy and reduced torque requirements
Evenly spaced planetary or recirculating rollers	Good operation in applications with changes of direction, stable friction torque	Low noise High degree of reliability
Recirculating roller screws with small lead down to 1 mm	High load carrying capacity, high axial stiffness that cannot be obtained with a ball screw of similar lead and diameter Very small input torque	High resolution, high stiffness, long service life, robustness

Fig. 1

Comparison of ball screws and roller screws contact area

Technical concepts

Introduction to SKF roller screws

Roller screws convert rotary motion into linear motion and vice-versa. Loads are transferred from the screw shaft to the nut through a roller set, therefore, roller screws relate to general bearing technology. Various types of bearing steel are used to attain the hardness and material fatigue properties required for carrying heavy application loads over extended periods of service. Certain bearing concepts such as load ratings, load cycles, nominal calculated life and service life, stiffness, speed ratings, lubrication requirements, etc. are explained below to guide customers through the roller screw selection process. The selection parameters are included in this chapter. To make the best selection of a roller screw, the designer should consider the following parameters such as the load cycle, the linear or rotational speed, the required life, the rates of acceleration and deceleration, the cycle rate, the environment, the lead accuracy, the stiffness, and any other special requirements.

For additional information about the roller screws selection process, please contact your local SKF representative.

Basic dynamic load carrying capacity C_a

The dynamic load carrying capacity is used to compute the nominal fatigue life of roller screws. It corresponds to the axial load, constant in magnitude and direction, concentric with the roller screw axis, under which the calculated nominal fatigue life as defined by ISO 3408–5 reaches one million revolutions.

Nominal fatigue life L_{10}

Nominal fatigue life L_{10} is, according to the ISO definition, the life attained or exceeded by 90% of a sufficiently large group of identical roller screws, working under identical conditions (alignment, axially and centrally applied load, speed, acceleration, lubrication, temperature and cleanliness).

The nominal life of a roller screw is the statistical number of millions of revolutions which the roller screw is capable of reaching before the first signs of flaking signifying material fatigue occurs on one of the rolling surfaces.

When reliability greater than 90% is required, the calculated nominal life must be corrected. See values for the correction factor in **table 1**. For example, if a reliability of 98% is required, $L_2 = 0,33 L_{10}$ where L_{10} is calculated using the formulae in **pages 111 to 113**.

Table 1

Correction factor for reliability		
Reliability [%]	Correction factor	L_n
90	1,00	L_{10}
95	0,62	L_5
96	0,53	L_4
97	0,44	L_3
98	0,33	L_2
99	0,21	L_1

Service life

The actual life achieved by a specific roller screw is known as service life. In addition to material fatigue, service life can be reduced by inadequate lubrication, wear, corrosion, contamination and, more generally, loss of the functional characteristics required by the application.

Experience with similar applications will help in selecting the right screw to obtain the desired service life. Structural requirements such as the strength of screw ends and nut attachments should also be considered.

To attain L_{10} life performance, the maximum cycle operating load F_{max} should not exceed 80% of C_a (for SR and SV product assortments) to limit the Hertzian pressure at the rollers/raceways contact points.

For small strokes (shorter than the nut length) or short oscillations, additional considerations such as the actual total number of loading cycles on any specific area of the shaft, and the false brinelling effect should be taken into account¹⁾.

Equivalent dynamic load F_m

The loads acting on the screw can be calculated according to the laws of mechanics if the external forces are known or can be calculated. For product sizing and selection, it is necessary to calculate the equivalent dynamic load: this is the hypothetical load, constant in magnitude and direction, acting axially and centrally on the screw, which, if applied, would have the same influence on the screw life as the actual loading conditions which the screw will be subjected to.

Radial and moment loads must be accommodated by linear guides. It is extremely important to resolve these possible problems early in the design stage. Radial forces are detrimental to the life and expected performance of the screw (→ **fig. 2**). Please refer to the chapter entitled *Recommendations for assembly*.

If misalignment, uneven loading, shock loads, etc. cannot be avoided, they must be taken into account during the sizing of the screw.

Their influence on the screw's nominal life can generally be estimated¹⁾.

Basic static load carrying capacity C_{0a}

Roller screws should be selected based on the basic static load carrying capacity C_{0a} , rather than the basic dynamic load carrying capacity, when they are subjected to continuous or intermittent shock loads while operating in stationary conditions for short periods of time.

The permissible load is determined by the permanent deformation caused by the load acting at the contact points. The static load carrying capacity is, according to ISO standards, the purely axially and centrally applied static load which creates, by calculation, a total (rolling element + threaded surface) permanent deformation equal to $1/10\,000$ of the curvature diameter of the rolling element.

In order to prevent surface damage, to keep smooth running and low noise level, SKF recommends that the application loads do not exceed 80% of the static load carrying capacity C_{0a} .

Usually the C_{0a} value corresponds to a Hertzian contact pressure ranging between 4 500 and 4 800 MPa.

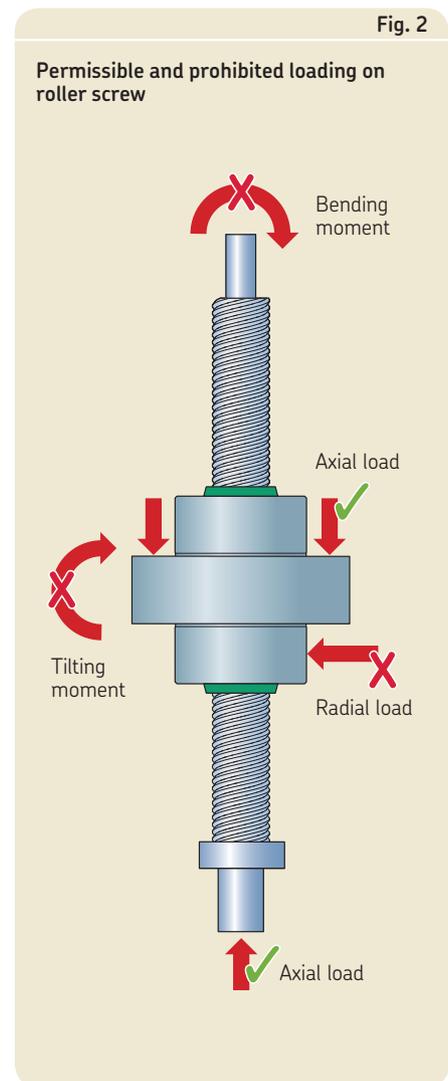

The basic dynamic and static load carrying capacities are related to the material properties, and vary with the material hardness at the contact points. Please refer to the paragraph explaining "materials, heat treatment and coatings" (→ **page 24**).

The basic static load carrying capacity must be, at a minimum, equal to the product of the maximum applied axial static load and a static safety factor s_0 . Past experience with similar applications and requirements of maximum static load occurrence, running smoothness and noise level will guide the selection of s_0 ¹⁾.

In order to prevent surface damage, to keep smooth running and low noise level, SKF recommends that the application loads do not exceed 80% of the static load carrying capacity C_{0a} , which equates to a static safety factor s_0 of 1,25.

For applications requiring high precision, roller screws should operate significantly below the static load carrying capacity, which means operation with a higher value for the static safety factor s_0 .

For heavily loaded applications where precision, noise level and running smoothness are not critical to the performance ex-

pectations, roller screws can operate at load levels close to the basic static load carrying capacity. With these conditions, special care must be paid to proper lubrication.

¹⁾ For additional information, please contact your local SKF representative

Critical rotating speed for screw shafts n_{cr}

A roller screw with the nut in a given position has a natural frequency of vibration in bending mode. When the screw shaft is rotating, it is important that the rotational speed not excite its natural frequency. If it does, it would result in elastic radial deflection of the shaft. In extreme conditions, without damping, the screw shaft could be bent. The natural frequency of the roller screw changes continuously as the nut moves along the shaft and in relation to the shaft supports. The positive effect of this axial nut displacement is that there is generally no time for the amplitude of the vibration at a given natural frequency to build up.

For calculation of the critical rotating speed, the shaft is the equivalent of a cylinder with an external diameter equal to the root diameter of the thread. The formula uses a parameter whose value is dictated by the mounting of the screw shaft ends, whether the screw shaft end is free, radially supported or fixed.

As a general rule, the nut is not considered to be a support for the screw shaft. Because of the potential inaccuracies in the mounting of the screw assembly, a safety factor of 0,8 is applied to the calculated critical speed.

Calculations where the nut is considered to be a support for the shaft or calculations which reduce the safety factor, require practical tests and possibly optimization of the design.

Permissible speed limit ($n d_0$) and acceleration

The permissible speed limit is the speed that a screw cannot reliably exceed at any time. It corresponds to the limiting speed of the rotation of rollers (SR and ISR types) or of the recirculation of the rollers (SV type) inside the nut. It is expressed as the product of maximum rotational speed n (r/min) and the nominal diameter d_0 (mm) of the screw shaft. The speed limits quoted in this catalogue are the maximum speeds that may be applied for short periods of time with optimized conditions of alignment, light external load or preload, and with appropriate lubrication.

Permissible speed limits for each technology:

- Planetary roller screw (SR) and inverted roller screw (ISR):
 $n d_0 \leq 160\,000$
- Recirculating roller screw (SV):
 $n d_1 \leq 30\,000$ for $d_1 \leq 25$ mm
 $n d_1 \leq 20\,000$ for $d_1 > 25$ mm

Running a screw continuously at the permissible speed limit may reduce the service life of the nut mechanism.

Important:

High speeds combined with high loads yield a relatively short nominal life¹⁾.

In the case of high accelerations, decelerations or fast movement reversal, SKF recommends either working under a nominal external load or applying a light preload to the nut to avoid roller sliding on the shaft.

The preload for screws subjected to high accelerations must be calculated to be sure that the rolling elements do not slide¹⁾.

However, excessive preload will generate an unacceptable increase in frictional heat.

Roller screws preloaded for optimum rigidity (PR or PV prefix) should not be operated continuously at high speeds.

Recirculating roller screws should not be operated at permanent high linear speeds or at their maximum speed rating. High speeds will be detrimental to the recirculation cam's life. In addition, noise levels will increase.

¹⁾ For additional information, please contact your local SKF representative

Efficiency η

Screw performance depends primarily on the geometry of the contact surfaces, their finish and the helix angle of the thread.

It also depends on the working conditions (load, speed, lubrication, preload, alignment, etc.)

Direct efficiency η is used to define the input torque required to transform the rotation of one component into the translation of another (\rightarrow **diagram 2**).

Conversely, indirect efficiency η' is used to define the axial load required to transform the translation of one component into the rotation of another one. It is also used to

define the braking torque required to prevent that rotation (\rightarrow **diagram 3**).

The reference coefficient of friction μ_{ref} would be achievable with perfect operating conditions of lubrication, alignment, etc. and it would result in generating a theoretical direct efficiency η , or a theoretical indirect efficiency η' . Because such laboratory conditions are not encountered with real applications, we define a practical coefficient of friction μ_{prac} used to estimate the practical efficiencies η_p and η'_p .

Practical efficiencies range between the starting efficiencies of a newly installed screw and that of a properly run-in screw. These practical values of efficiency are calculated with a practical value for the coefficient of friction μ_{prac} .

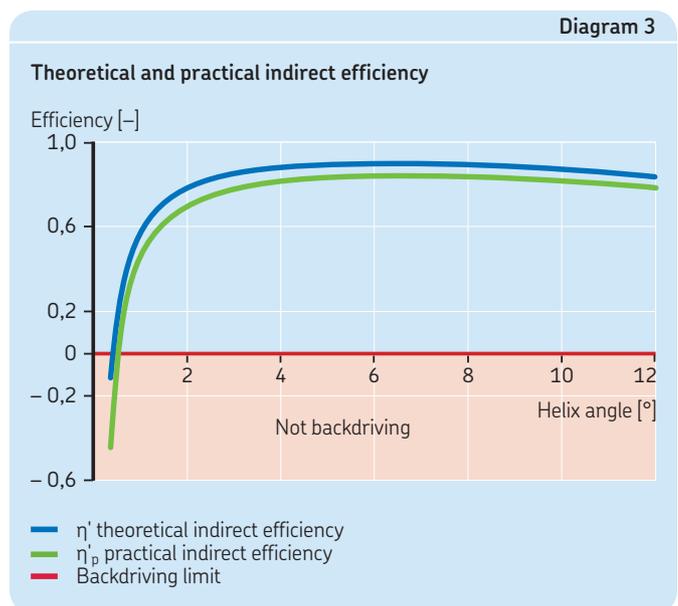

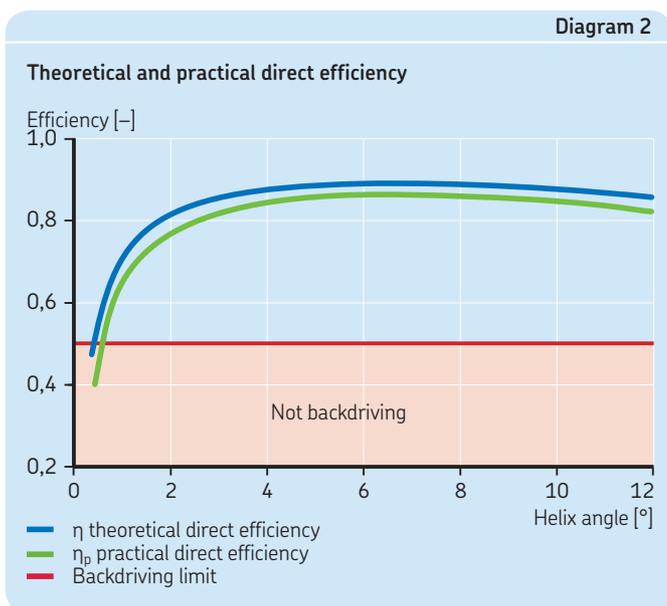

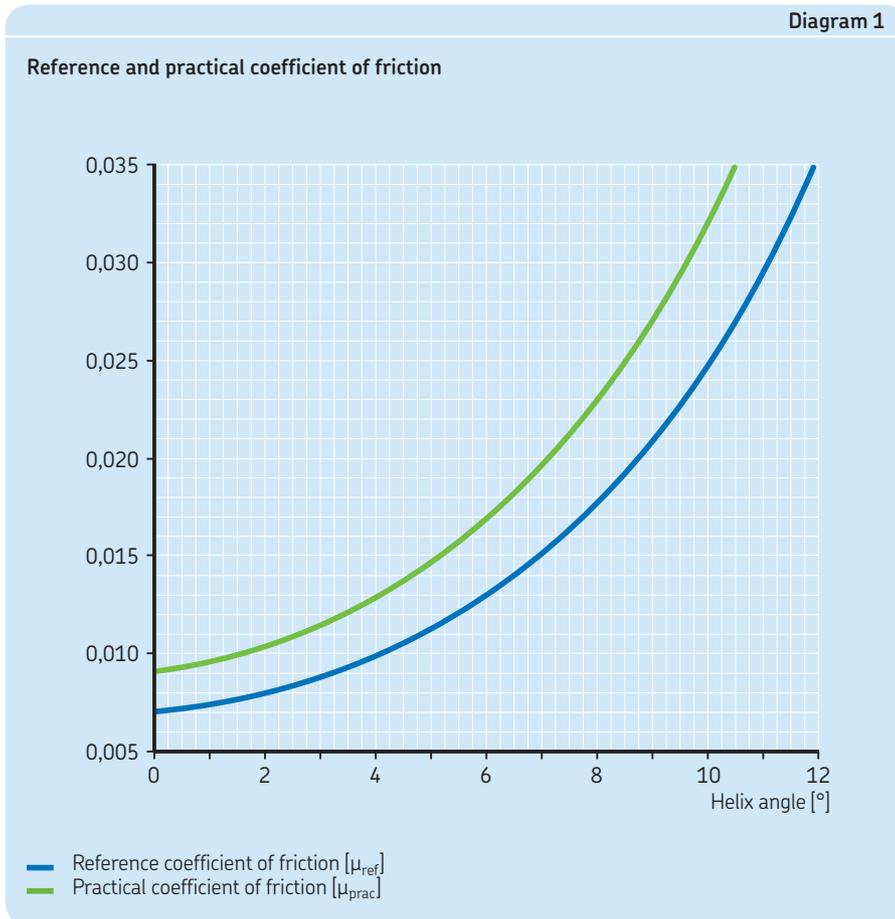

To account for real installation, running conditions and the experience of real life application, this practical coefficient of friction μ_{prac} corresponds to the reference coefficient of friction μ_{ref} increased by 30% (\rightarrow **diagram 1**).

This calculation method reduces the practical efficiency of the screw versus its theoretical efficiency by about 5%.

Generally, the practical efficiency increases with speed, and over time with running in effect.

Note:

The helix angle alpha can be calculated using formula **pages 112**.

Back-driving and braking torque T_b

Except for one specific recirculating roller screw dimension (SV 50 × 1) and for some specific sizes of inverted roller screws, roller screws are reversible or can be back-driven under most circumstances.

A braking mechanism (gear reducer or brake) must be part of the design if back-driving is to be avoided.

If back-driving is required, special care must be taken to align the whole system. Misalignment significantly increases the coefficient of friction by tilting and, consequently, increases the axial force required to back-drive the mechanism.

Attention:

Vertical installations and applications presenting a risk of falling loads require special care by designers and users. It is the customer's responsibility to determine the need for back-up locking devices and safety systems.

Break away torque T_x

This is the amount of torque required to overcome the following forces to start rotation:

- (a) The total inertia of all moving parts accelerated by the source of power (including rotational and linear movements)
- (b) The internal friction of the screw/nut assembly, bearings and associated guidance systems.

In general, the torque required to overcome inertia (a) is greater than the friction torque (b). The coefficient of friction μ_s for a high-efficiency screw, when it starts moving, is estimated to reach up to twice the amount of the practical dynamic coefficient of friction μ_{prac} , under normal operating conditions.

Driving torque T_t

This is the total torque required from the electric motor to overcome inertia, external forces, preload, friction, etc. Please see calculation formulae on **pages 111 to 113**.

Static axial stiffness R_t

The static axial stiffness of a complete roller screw assembly is the ratio of the external axial load applied to the system and the axial displacement of the face of the nut in relation to the fixed (anchored) end of the screw shaft. The inverse of the system's overall stiffness is equal to the sum of all inverted values of stiffness for each component (screw shaft, roller nut, support bearings, etc.)

Therefore, the overall stiffness of the system is always lower than the lowest value for stiffness of any individual component.

Nut stiffness R_n

When a preload is applied to a nut, the internal play is eliminated. Additionally, the squeeze load responsible for generating the preload creates initial Hertzian elastic deformation at the contact points. This leads to an increase in stiffness proportionate to the preload value.

The theoretical elastic deformation at the contact points does not take into account machining inaccuracies, actual sharing of the load between the different contact surfaces, or elasticity of the nut and screw shaft.

For this reason, two stiffness values are given in the catalogue:

- R_{ng} : This is the minimum nominal stiffness reached by any nut and roller assembly. This value, based on laboratory measurements, is a practical value and does not require any correction factor. It takes into account production tolerances, actual load sharing, preload torque tolerance, deflection of the nut body, etc. It can be used to calculate the total stiffness during the roller screw selection process.
- R_{nr} : This value corresponds to the reference nominal stiffness of a nut and roller assembly with all geometrical dimensions centered within the tolerances. It corresponds to the optimum stiffness level.

R_{nr} is always greater than R_{ng} . Both values are determined by applying an external axial load, centered on the screw shaft and equal to twice the preload force.

Shaft stiffness R_s

The elastic deformation of the screw shaft is proportional to its length and inversely proportional to the square of its root diameter.

According to the relatively low stiffness of the shaft, an increase of the nut preload (and its stiffness) will, in most cases, not increase significantly the overall stiffness of the system.

Consequently, the preload stated in the catalogue for each screw dimension is the maximum and should not be exceeded.

Materials, heat treatment and coatings

Choice of steel material

Standard screw shafts are mainly manufactured from pre-treated 50CrMo4 (otherwise 42CrMo4) which is surface hardened by induction. Through hardened 100Cr6 bearing steel is used for nuts and rollers.

100Cr6 can also be selected for the screw shaft for operation at higher temperature up to 180 °C, or if the application presents a concern for wear.

Material properties are detailed in **table 3**.

Stainless steel can be used for all types of roller screws. For non-magnetic specifications and for high corrosion resistance requirements, nickel and cobalt based alloys can be used. Properties offered by these special steel variants are summarized in **table 2**.

Table 2

Selection of stainless steels			
Steel (ISO standard)	Description	Shaft hardness [HRC]	Relative corrosion resistance
X105CrMo17	Martensitic stainless steel	58–60	**
X30Cr13	Martensitic stainless steel	50–55	***
X12CrNiMoV12–3	Carburizing stainless steel	58–60	***
X40CrMoVN16–2	Nitrogen stainless steel	58–60	****
X5CrNiCuNb16–4	Precipitation hardening stainless steel	38–45	*****
X17CrNi16–2	Martensitic stainless steel	40–45	*****
Inconel 718	Nickel base alloys	41–43	*****
Alacrite 602	Cobalt base alloys	41–43	*****

Table 3

Selection of standard steels						
Component	Steel	Supplying state	Heat treatment	Maximum allowed operating temperature	Surface hardness at standard tempering temperature [HRC]	Customer benefits
Standard shaft	50CrMo4 or 42CrMo4	Pre-treated Tensile strength 880 to 1 030 MPa Yield strength > 650 MPa	Induction hardening	110 °C	58 to 60	Good wear resistance Resilience
Standard shaft on request	50CrMo4	Pre-treated Tensile strength 880 to 1 030 MPa Yield strength > 650 MPa	Induction hardening Higher tempering temperature	150 °C	58 to 60	Good wear resistance and medium temperature operation Resilience
Special shaft	100Cr6	Pre-treated Tensile strength 840 to 970 MPa Yield strength > 500 MPa	Induction hardening	180 °C	59 to 63	Higher wear resistance, adapted to higher operating temperature but more brittle
Nut & rollers	100Cr6	Annealed	Through hardening	180 °C	58 to 62	Good wear resistance and high temperature operation

Effect of surface hardness on roller screw basic load rating

According to the ISO reference calculations, the load ratings provided in the catalogue are given for surface hardness above 654 HV (58 HRC). For materials or treatments resulting in a lower hardness, correction factors should be applied to the dynamic and static load carrying capacities:

$$C_{a \text{ corrected}} = C_a \left(\frac{HV_{\text{actual}}}{654} \right)^2$$

$$C_{0a \text{ corrected}} = C_{0a} \left(\frac{HV_{\text{actual}}}{654} \right)^3$$

Note:

654 HV is equivalent to 58 HRC

Surface coatings

SKF offers various types of surface coatings for improved roller screw performances:

- Manganese phosphate coating of carbon steels to improve corrosion resistance
- Low friction coating is available on request¹⁾.

Operating temperature

Operating at high temperatures will lower the steel hardness, alter the thread accuracy, may increase the oxidation of the materials and change the lubricant properties.

With operating temperature lower than -20 °C, the core resilience of the material can become critical. The lower the temperature, the more brittle the material becomes, especially with a long or thin screw shaft. Bending stresses or shock loads increase the risk of fractures.

Applications with high cycling rates and high loads can generate excessive amounts of heat. To eliminate excess heat, SKF can provide a nut mechanism, with cooling chambers. When connected to a customer supplied water circulation system, temperatures can be stabilized, enabling higher cycling rates and increased productivity.

Screw shaft buckling or column strength F_c

The column loading of a screw shaft must be checked when it is subjected to dynamic or static compression loading.

The maximum permissible compressive load is calculated using the Euler formulae, with a safety factor of 3 to 5, depending on the application. The type of shaft end mounting is critical for selecting the proper coefficient to be used in the Euler formulae.

When the screw shaft has a single diameter along its total length, the root diameter of the threaded shaft is used for the calculation. When the screw shaft comprises different sections with varying diameters, calculation becomes more complex¹⁾.

Through hardening treatment

¹⁾ For additional information, please contact your local SKF representative

Shaft design

It is possible to deliver screws with one end larger than the shaft outside diameter d_1 . This design feature is frequently used in conjunction with support bearings with large bore diameter.

To grind the thread efficiently, an undercut with root diameter d_2 and length l_2 is needed (→ fig. 3 and table 4).

Designing the screw shaft ends

Customers designing their screw shaft ends are responsible for checking their strength against static and dynamic operating conditions.

The simple approach considers the shaft end diameters. Stress concentration factors must be used.

Zone A must be checked for strength against torsion and zone B must be checked for strength against torsion and tension (→ fig. 4).

Important:

Application loads reaching the basic load rating C_a generate very high mechanical stresses on the shaft ends. SKF strongly recommends that shaft ends be calculated with extreme care for such applications.

Table 4

Type of roller screw	Design conditions	Value for l_2
SR, BR, PR, HR, SRR	$d_3 \leq 1,85 d_1$ Lead $P_h \leq 8$ mm	$l_2 \geq 12$ mm
	$d_3 \leq 1,85 d_1$ Lead $P_h > 8$ mm	$l_2 \geq 1,4 P_h$
SV, BV, PV	$d_3 \leq 1,85 d_1$ Lead $P_h = 1$ mm	$l_2 \geq 12$ mm
	$d_3 \leq 1,85 d_1$ Sizes $d_0 P_h = 40 \times 2$ or 50×2 or 63×2 mm	$l_2 \geq 12$ mm
	$d_3 \leq 1,85 d_1$ All other types of recirculating roller screws	$l_2 \geq 14$ mm
All types of roller screws	$d_3 > 1,85 d_1$	Please contact your local SKF representative

Fig. 3

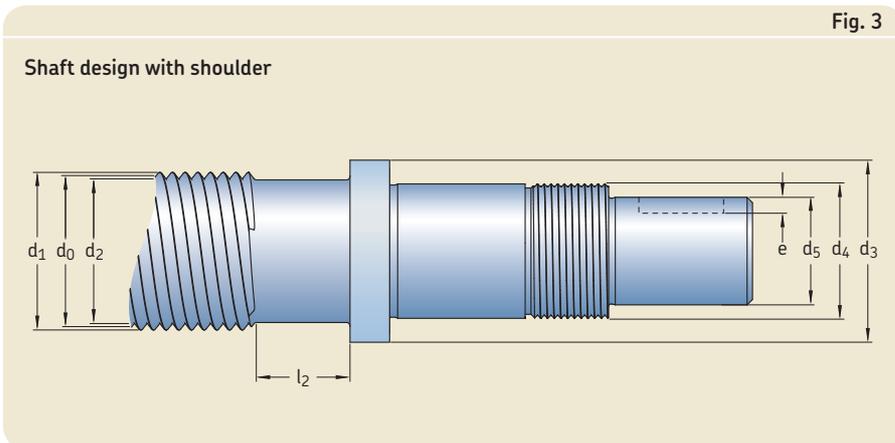

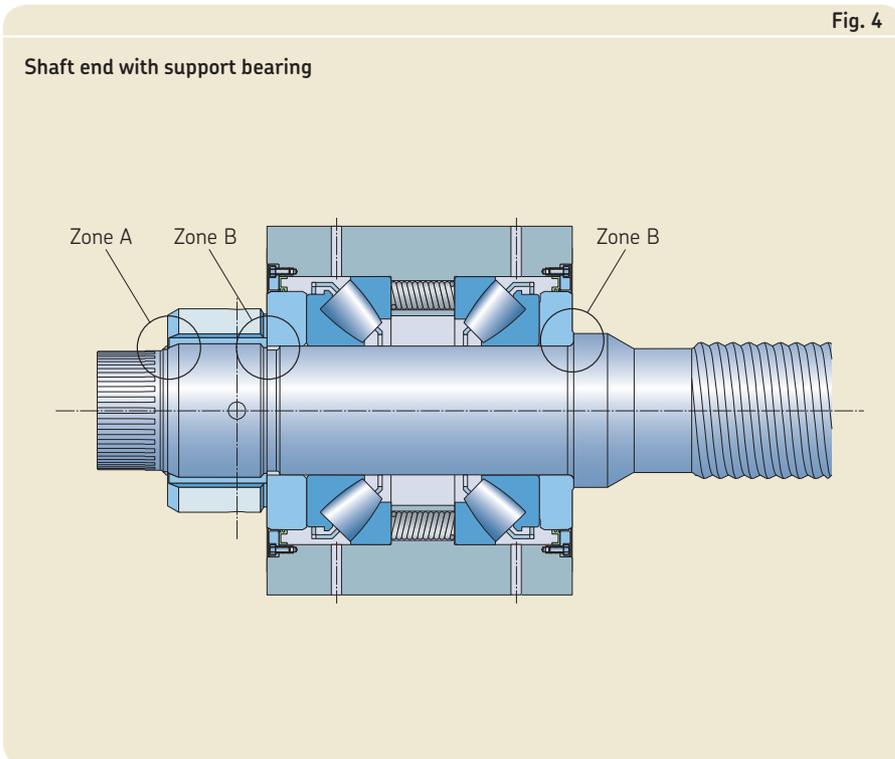

Fig. 4

Zone A: Torsion only

The nominal shear stress τ caused by the input torque T is given by:

$$\tau = \frac{16\,000\,T}{\pi d_5^3}$$

This value is increased by a stress concentration factor f_4 to give the real shear stress τ_p

τ_p

$$\tau_p = f_4 \tau$$

According to von Mises, the total stress σ_t

$$\sigma_t = 1,73 \tau_p$$

For safety, σ_t should be less than 67% of the yield strength.

If the end diameter d_5 includes a keyway of depth e , calculate using $(d_5 - e)$ instead of d_5 .

The angle of twist of the screw shaft is given by

$$\theta = \frac{7,48\,T\,l}{d_0^4}$$

where

l = length between motor and nut

The linear positioning error, δ , caused by this twist is

$$\delta = \frac{P_h \theta}{360}$$

Note:

Stress concentration factors f_4 and f_5 are available in all general mechanical literature.

Units:

d : mm

τ : N/mm² [MPa]

σ : N/mm² [MPa]

θ : degree [°]

δ : mm

F : N

Zone B: Axial + torsional stresses

The nominal axial stress caused by the axial load F is given by

$$\sigma = \frac{4\,F}{\pi d_4^2}$$

This value is increased by a stress concentration factor f_5 to give the real principal stress σ_p

$$\sigma_p = f_5 \sigma$$

As for zone A calculation

$\tau_p = f_4 \tau$

$$\tau_p = f_4 \tau$$

According to von Mises, the total stress σ_t

$$\sigma_t = (\sigma_p^2 + 3 \tau_p^2)^{1/2}$$

For safety, σ_t should be less than 67% of the yield strength.

Product inspection and certification

Standard or special inspection reports or certificates can be provided on request. The following reports can be supplied with roller screws:

- 1 Conformity with customer specifications (fl. EN 10204)
- 2 Conformity with catalogue specifications (fl. EN 10204)
- 3 List of manufacturing and control operations
- 4 Preload torque curve or internal friction torque curve
- 5 Lead precision curve
- 6 Matching of travel deviation
- 7 Stiffness curve
- 8 Raw material chemical analysis
- 9 Magnetic particle inspection
- 10 Through hardening heat treatment
- 11 Induction hardening
- 12 Carburizing hardening
- 13 Surface treatment
- 14 Report for specific dimensions
- 15 FAIR (First Article Inspection Report) EN9102

Working environment

As a stand-alone component, the roller screws cannot be ATEX certified.

Consequently, SKF does not recommend the use of roller screws in explosive environments.

Lubrication

Lubrication for roller screws

The primary objectives of lubrication are:

- To prevent metal-to-metal contact between the rolling surfaces, and to minimize metal fatigue
- To protect against corrosion
- To minimize wear
- To maximize the roller screw service life
- To achieve performance requirements for given operational conditions (temperature, humidity, vacuum environment, corrosive environment, etc.)

In standard delivery conditions, roller screws are not lubricated. However, they can be lubricated on request. Please contact your local SKF representative. For roller screws with standard delivery conditions, customers must provide proper lubrication prior to operation.

Important:

Before shipping, roller screws are coated with a rust inhibitor. The inhibitor is not a lubricant. Depending on the lubricant selected for the application, it may be necessary to remove the rust inhibitor before applying the lubricant in order to eliminate any risk of incompatibility. To remove the film, SKF recommends the following procedure:

- Wash the roller screw assembly with a solvent
- Allow the solvent to penetrate the nut assembly
- Let the solvent drain completely from the roller screw assembly

The rust inhibitor SKF applies to its roller screws is not compatible with the following lubricants:

- Polyglycol base oil
- Ester base oil
- Silicone base oil
- Aluminum complex soap

If any of the above lubricants are used, please follow the procedure above to remove the rust inhibitor prior to lubrication.

There are three main types of lubricants, grease, oil and dry lubricant. In the majority of applications, grease or oil lubrication will be selected. Due to similar tribological conditions, most greases or oils recommended for gears and bearings are also suitable for roller screw lubrication (→ table 5).

Table 5

Different lubricant pros and cons

Type of lubricant	User benefits	Constraints
Grease	Most practical and most usual lubrication solution for roller screws	Requires relubrication schedule
Oil	Higher lubrication performance for roller screws Circulating oil helps to clean the roller screw mechanism and stabilize the operating temperature	Requires more complex equipment installation Special care required for equipment cleanliness and tightness
Dry coating	Lubrication solution for specific applications or environments where liquid lubricants cannot be used	Requires advanced processing method Might require special steel variants for roller screws Higher cost Well defined operating conditions to achieve expected performance

Grease lubrication

Grease is the most common lubricant for screws. The grease type is primarily selected based on the requirements for operating temperature, load level, speed and environment.

Grease consists of base oil (average 80% of total grease volume) which is the lubricating agent, contained in a thickener matrix or soap, plus additives which provide special properties.

Grease selection

Grease with a synthetic base oil is recommended over grease with a mineral base oil as it presents the advantages of greater stability over time and lower viscosity variation with changes of temperature.

The following synthetic oils provide good results for roller screw applications:

- Polyalphaolefins (PAO)
- Polyglycol (PAG)

Among many possible alternatives, the following thickeners achieve a good result with roller screw applications:

- Lithium or complex lithium
- Barium or complex barium

The dynamic viscosity characterizes the oil's ability to create a sufficiently thick hydrodynamic film between the contact surfaces of a screw. Lubricant data sheets usually provide the viscosity of the base oil at 40 °C and 100 °C.

In general, SKF recommends lubricants with a viscosity around 100 Cst when the application has reached its normal operating temperature.

Normal operating temperature is determined by the heat generated by the roller screw, any externally applied heat and the amount of heat that can be transferred away from the screw.

Grease consistency or NLGI grade between 0 (semi-fluid) and 2 (soft) is suitable for most applications. For automatic lubrication systems, SKF recommends checking the consistency required for the system to work properly.

For high speed applications and vertical applications which could cause the lubricant to fly off or pour down the shaft because of centrifugal forces, lubricants that will strongly adhere to the shaft are recom-

mended. In this respect, barium soap and complex metallic soaps provide good adhesive properties. In these conditions, NLGI grade 2 is also recommended to provide good consistency.

However, when rotating speed is low (below 10 r/min), high viscosity lubricants are recommended to enable the creation of a sufficiently thick hydrodynamic film between the rolling surfaces, and to limit friction under load. SKF usually recommends a viscosity above 300 Cst at the operating temperature.

Shearing of the hydrodynamic lubricant film is proportional to the load level. In general, for external load levels greater than 25% of the dynamic load carrying capacity of roller screws, SKF recommends greases with extreme pressure (EP) additives.

Greases that pass the "four balls welding load test" under a weight of 250 kg, will perform well in heavily loaded applications.

The following working conditions require specific greases:

- Food industry
- Vacuum applications
- Presence of water
- Vibrations
- Small movements, oscillations...

SKF lubrication systems can be adapted to most roller screws for automatic injection of grease.

Lubrication schedule and procedure

SKF recommends the following lubrication schedule and procedure:

1 Commissioning and initial lubrication

New roller screws must be lubricated prior to use.

1.1 Lubrication procedure for the shaft: On the threaded length of the shaft, spread a volume of grease with a brush. The product tables (**pages 52 to 101**) provide the quantity of grease Z_s to be applied per meter of threaded length for each screw size.

This volume of grease is estimated using the following formula:

$$Z_s = 4,4 \times 10^{-4} d_0 l_1$$

where

Z_s = grease volume [cm³]

d_0 = nominal diameter of the screw [mm]

l_1 = threaded length of the screw [mm]

1.2 Lubrication procedure for the nut:

Roller screws with a flanged nut have a threaded hole for a grease fitting. Roller screws with a cylindrical nut include a central groove and a lubrication hole that can be connected to a grease channel through the housing. During the initial lubrication, SKF recommends filling $\frac{1}{3}$ rd of the free space in the nut with grease. The volume of grease to be injected is listed in the product tables in column Z_n .

Inject the grease in several steps, rotate the nut on the shaft or the shaft in the nut (several revolutions) between two grease injections in order to spread the grease between the rollers and to spread it over the nut length.

2 First relubrication

For non-preloaded screws, SKF recommends an additional injection volume of $Z_n/2$ after 100 000 revolutions.

3 Lubrication maintenance schedule (after the first relubrication)

The following method describes the lubrication maintenance schedule and procedure for complete grease renewal, to be followed for the life of the roller screw, after the initial greasing operation and the first relubrication. This recommendation will optimize performance and extend the service life of the roller screw. This method is valid for screws working in an industrial environment, in a workshop, without external contaminants, and at ambient temperature not exceeding 40 °C.

A lubricant that does not completely meet the application requirements will require shorter relubrication intervals.

To avoid problems associated with grease compatibility (miscibility), always use the same type of grease. If, for whatever reason, it is necessary to switch to a different type of grease, check miscibility carefully.

When in doubt, thoroughly clean the nut and screw shaft.

Note:

Grease applied to the length of the screw thread is usually not protected, which can accelerate aging and oxidation.

The parameters determining the relubrication intervals are:

- Speed: maximum rotational speed of the application
- Load: mean axial load carried by the screw in the application. The mean load can be calculated using the formulae detailed in **pages 111 to 113**
- Temperature: internal temperature of the nut mechanism, usually the temperature measured on the outside surface of the nut, plus 15 °C.

If idle time is very long compared to operational time, the natural ageing and oxidation of the grease tends to change the grease condition, and decrease relubrication intervals. This case is not in the scope of following method.

The initial quantity of grease is the volume spread on the shaft plus the volume injected in the nut.

$$Z_0 = Z_s + Z_n$$

The calculation of the lubrication intervals takes into account the actual operational

time when the screw is in motion (idle time is not factored into that calculation).

The time before renewal of the initial quantity of grease is:

$$t_g = t_s K_T K_F$$

where

t_g = Operational time before complete renewal of the initial quantity of grease

t_s = Basic relubrication interval related to maximum speed. K_s can be estimated using **diagram 4**

K_T = Correction factor related to roller screw maximum internal operating temperature. K_T can be estimated using **diagram 5**. This diagram applies to standard greases such as lithium based greases

K_F = Correction factor related to screw mean operating load. K_F can be estimated using **diagram 6**, with consideration to the ratio of equivalent dynamic load to dynamic load carrying capacity F_m/C_a .

Important:

The renewal of grease should be done incrementally. Once the relubrication quantity and total interval are determined, they must be fractioned over time in practical volume and intervals. SKF recommends applying small amounts of grease frequently rather than applying the full quantity in one operation.

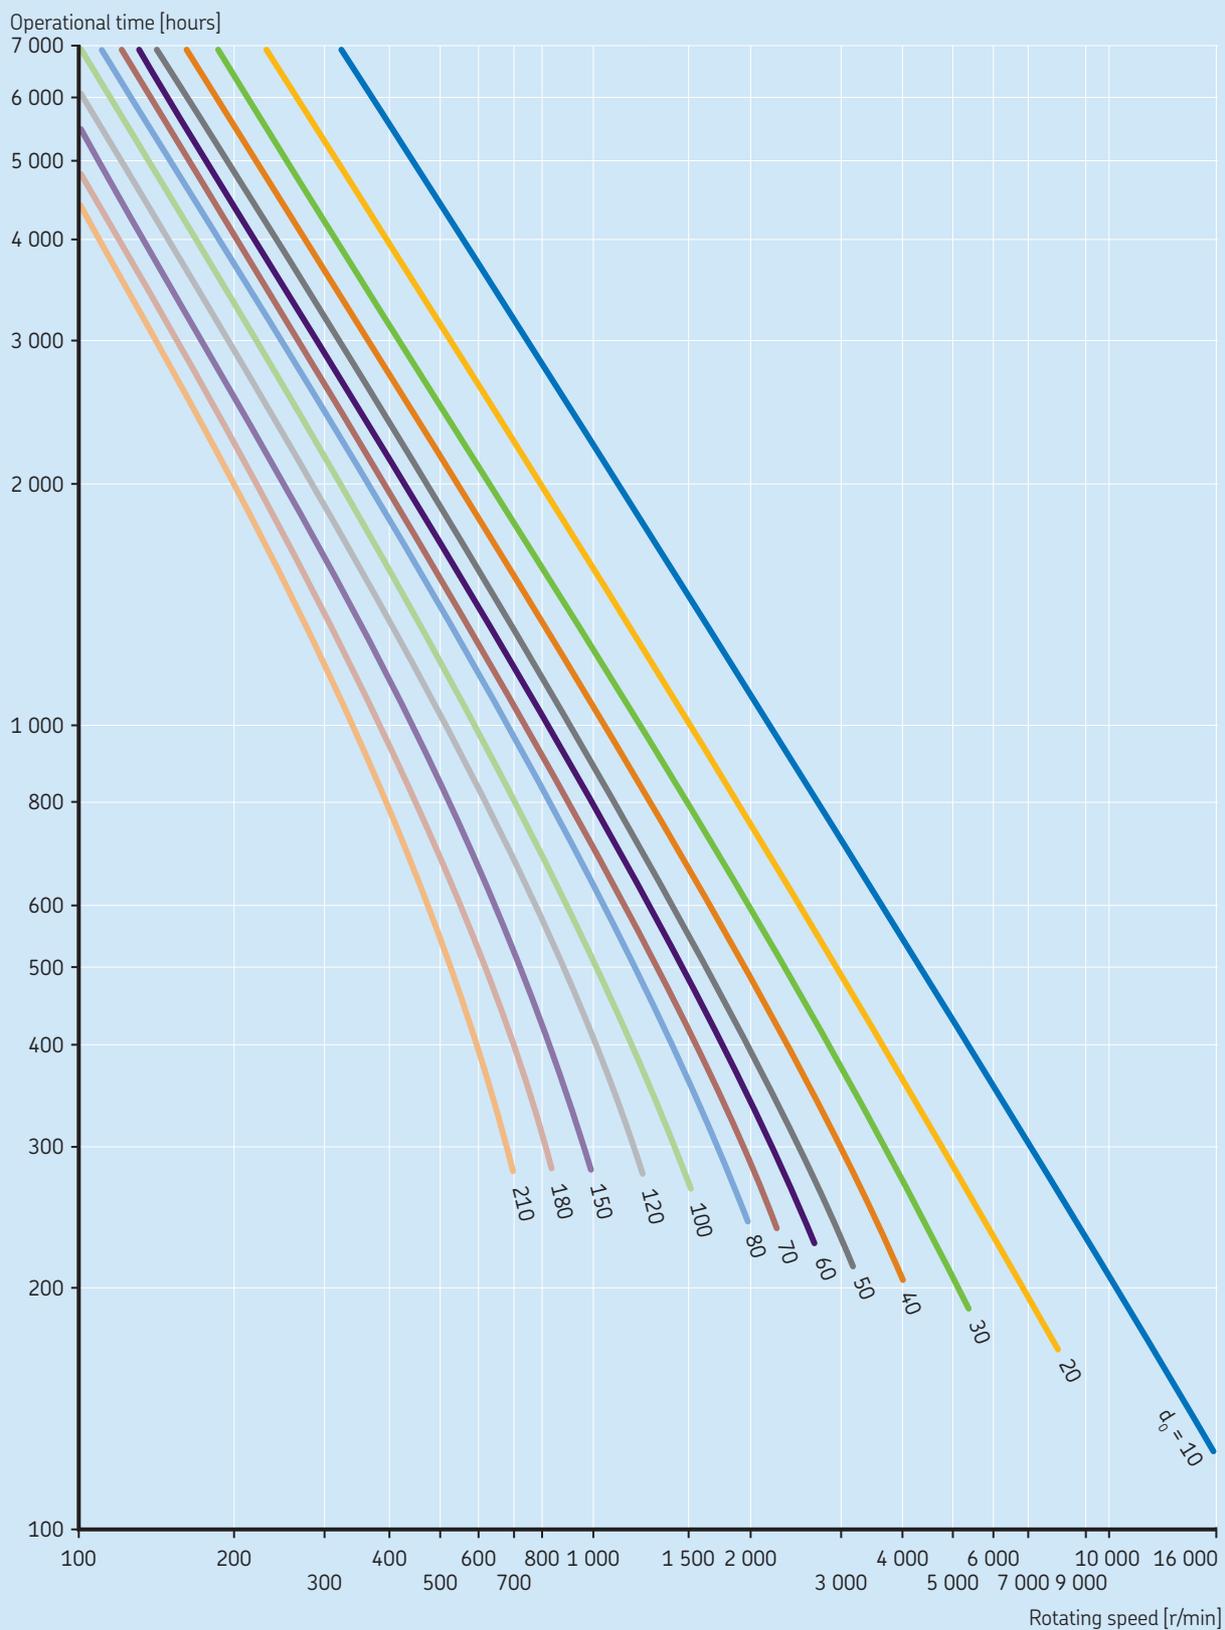

If all the grease is renewed at once (which is not recommended), operate the roller screw at low speed to spread the grease over the full length of the screw.

If the consistency or viscosity of the grease changes rapidly, or if the temperature does not stabilize to an acceptable level, either the relubrication intervals must be shortened, or the grease is not suitable for the application conditions and another type of grease must be used.

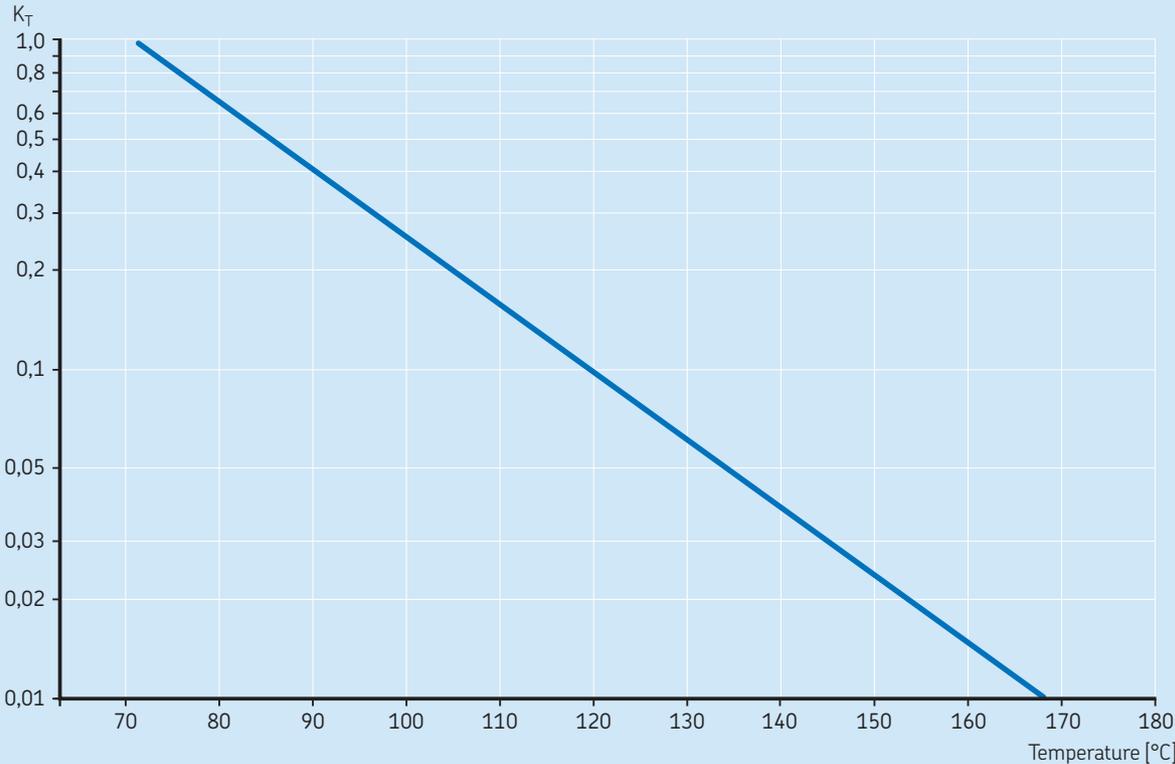

Always rotate the shaft during periodic lubrication to distribute the grease evenly in the nut and the shaft. Rotating the shaft also prevents a roller from blocking the grease inlet hole.

Basic relubrication interval t_b as a function of

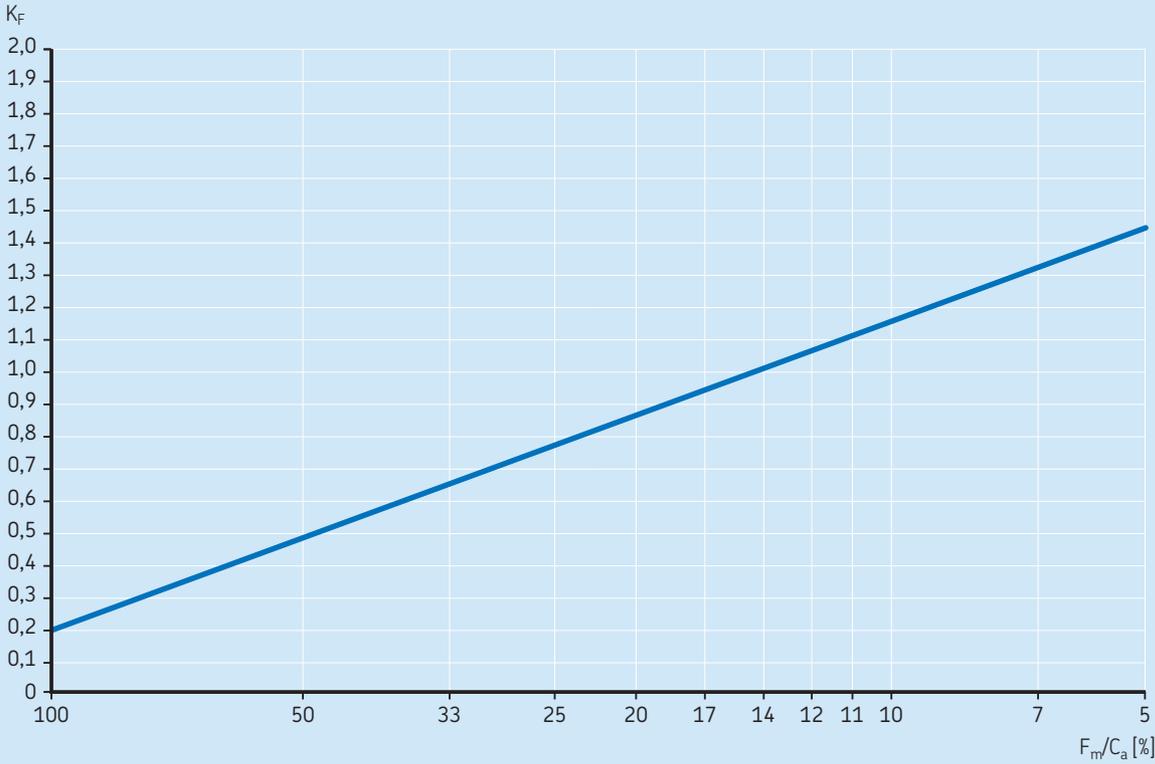

- rotating speed [r/min]
- operational time [hours]
- nominal diameter d_0 [mm]

Correction factor K_T for operating temperature

Correction factor K_F for mean operating load

Example:

Roller screw SRF 39 × 20R 760/1030 G5 Z WPR is used in a simulator, in the vertical position, and operates according to following conditions:

- Mean axial load over one working cycle = 17 kN
- Each working cycle accomplishes 32 back-and-forth strokes of 1 000 mm (total travel of 32 000 mm per working cycle), operation is 12 working cycles per hour, 8 hours per day
- The screw is in motion during 70% of the time of a working cycle, i.e. 5,6 hours of motion per day
- Maximum speed = 1 500 r/min

For such application data, a grease with metallic complex soap or barium is recommended because it will improve adhesion under high speed and vertical position. A viscosity of 100 to 150 Cst at 40 °C is advised.

Initial quantity of grease when commissioning the screw

- Initial quantity of grease on the shaft
 $Z_s = 4,4 \times 10^{-4} d_0 l_1$
 $= 4,4 \times 10^{-4} \times 39 \times 760$
 $= 13 \text{ cm}^3$ (see product table)
- Initial quantity of grease in the nut
 $Z_n = 28 \text{ cm}^3$ (see product table)
- Total quantity of grease
 $= 13 + 28 = 41 \text{ cm}^3$ must be applied

Calculation of first relubrication

- With the given duty cycle, 100 000 revolutions are reached within one day
- $(32\ 000 / 20) = 1\ 600$ revolutions per working cycle
- 12 cycles per hour \Rightarrow 19 200 revolutions per hour
- 8 hours operation per day \Rightarrow 153 600 revolutions per day
- Approximately 1 day into operation, the first relubrication should be scheduled with 14 cm³ of new grease in the nut (half the initial volume of grease in the nut).

Calculation of lubrication maintenance schedule

- t_s :
 Maximum speed = 1 500 r/min
 From **diagram 7**, with 1 500 r/min and $d_0 = 39 \text{ mm} \Rightarrow K_S = 680 \text{ hours}$
- K_T :
 The temperature measured on the nut external surface = 65 °C
 \Rightarrow Internal screw nut temperature = 80 °C
 From **diagram 8** $\Rightarrow K_T = 0,65$
- K_F :
 Dynamic load carrying capacity C_a of SRF 39 × 20R = 172 kN
 $F_m / C_a = 17 / 172 \approx 10\%$
 From **diagram 9** $\Rightarrow K_F = 1,15$

Therefore, the maintenance lubrication schedule is:

- $t_g = t_s K_T K_F$
 $= 680 \times 1,15 \times 0,65$
 $= 508 \text{ hours}$
 $= 90 \text{ working days } (508 / 5,6 \approx 90)$
 Within a period of 90 days, 41 cm³ of new grease must be applied, to be divided in fractions applied on a regular basis.

Diagram 7

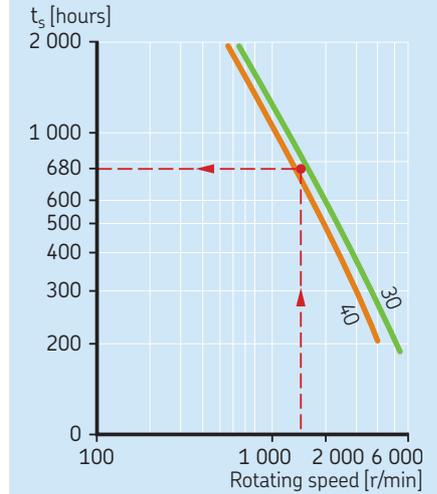

Diagram 8

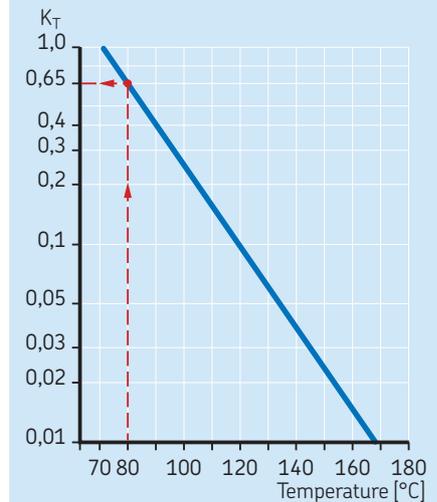

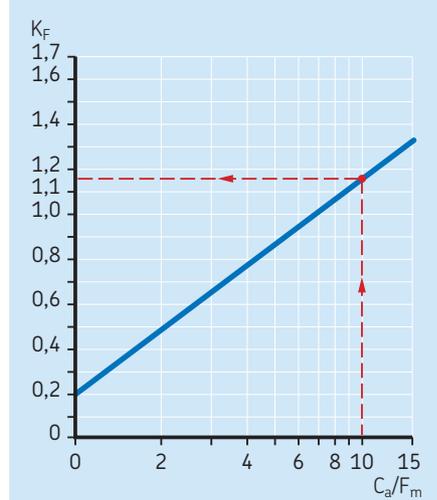

Diagram 9

Oil lubrication

Oil lubrication provides the following advantages over grease lubrication.

Oil dissipates heat more efficiently than grease, particularly when there are heavy duty cycles and/or high speeds.

It helps to remove contaminants, and helps to clean the roller screw nut.

Lubricating a roller screw with oil is normally accomplished using a centralized recirculating oil system. This type of system is ideal because it continuously replaces the oil in the nut with cooled filtered oil coming from the reservoir. This system is recommended to control the flow of lubricant, remove any contaminants and avoid overheating.

Oil selection

Oils used to lubricate other rotating parts such as bearings and especially gears can also be used to lubricate roller screws. Using hydraulic oils will jeopardize the product performance, condition and life.

The oil performance is affected by the rotational speed, the operating temperature and the load level.

The oil should have a viscosity of 100 Cst at the operating temperature. At low speed (below 10 r/min), the viscosity should be \approx 300 Cst at the operating temperature.

EP additives are recommended to improve the oil film strength.

Corrosion resistant and stabilizing additives are also recommended. Synthetic oils (PAO, polyglycol or ester based) are recommended for long service life and stable operation at high temperatures.

Oil quantity

The quantity to be injected will depend on the size of the roller screw, the speed, the duty cycle and the sealing efficiency of the wipers. It can vary from 0,5 to 100 cm³/hour, with small injections of 0,1 to 1 cm³. It is best to adjust, by experience, the oil flow to obtain the correct stabilization temperature.

Wipers

Wipers are composite components fitted at the ends of the nut with the purpose of preventing contamination and keeping the lubricant in place. Wipers are important components for roller screw performance and service life. It should be noted that standard wipers perform like labyrinth seals, not like garter seals. Depending on the product assortment, wipers are standard or optional (→ fig. 5).

Standard wipers are manufactured from acetyl resin with continuous operating temperature up to 110 °C and peak temperature up to 140 °C (→ tables 6 and 7).

Important:

Normally, threaded wipers are not axially secured in the nut. If the maximum stroke position is not respected and the edge of wiper extends beyond the non-threaded portion of the screw, the wiper can disengage from the nut or potentially jam. For this reason, the user shall respect the maximum stroke position.

On request, wipers can be axially secured to a nut to prevent disengagement of the wipers during operation.

Dry lubricants

When wet lubrication is not allowed or not effective (application examples: satellites, laboratories), dry lubricants present the following advantages:

- Low out-gassing (for example, satellite applications)
- Coefficient of friction independent of speed and temperature
- Positional stability
- Low rate of ageing (for example, during long storage periods)

Dry lubricants can be applied by projection, electrolytic deposit or physical vapour deposit.

SKF recommends thin deposits that will support a low coefficient of friction: these dry lubricants are usually based on PTFE, MoS₂, WS₂, graphite. These coatings are not corrosion resistant, and special care must be taken when selecting raw materials.

SKF also recommends thin deposits that enhance the resistance to wear. Such dry lubricants are typically based on tungsten carbide, Diamond Like Carbon or chrome plating. They do not provide the low coefficient of friction of PTFE for example.

Dry lubricants (on a stand-alone basis) are not suitable for industrial grade or for heavy duty applications, and they cannot reach the rolling fatigue life achieved with grease or oil lubrication.

Note:

Lubrication that is performed at the customer facility after product delivery is outside the control of SKF. However, SKF provides the above guidelines to aid the customer in selecting a lubricant, and proper maintenance to provide maximum performance and product life. For additional information about lubricants and lubrication systems, please contact your local SKF representative.

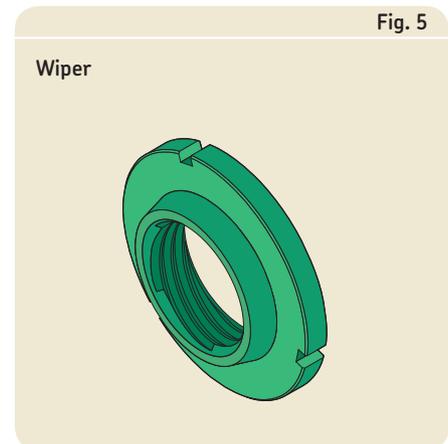

Table 6

Standard wipers	
Roller screw types	Wipers in standard delivery (Acetyl resin material)
Planetary SR/BR/PR	To be specified in the designation
Planetary Ultra Power HR	Included
Planetary IR (inverted)	Not included and not an option (wipers cannot be fitted into this roller screw design, sealing can be integrated into the push tube)
Planetary SRR (rotating nut)	Included (wipers fitted in the roller screw nut, garter seals fitted in the bearings housing)
Recirculating SV/BV/PV	To be specified in the designation

Table 7

Special wipers	
Optional wiper design	Application
PTFE material	High operating temperatures: continuous temperature up to 200 °C, peak temperature up to 260 °C
Tighter wiper	Higher resistance to contaminants and better lubricant retention inside the nut
Split (two half moons)	Easier wiper disassembly on long, large diameter screws

Axial play and preload

Axial play and preload

Standard roller screws are manufactured with axial play which varies between 0,02 mm and a maximum of 0,1 mm, depending on product size.

Roller screws can be manufactured without backlash or with preload (→ **table 8**).

For optimum stiffness and positioning accuracy during reversal of loading direction, or during operation with low external load, internally preloaded nuts are recommended. Under these conditions, preloaded nuts exhibit a much lower axial deflection and much higher stiffness than non-preloaded nuts.

All preloaded roller screws (PR and PV types) are run in before delivery to the customer. This process stabilizes preload and stiffness and virtually eliminates backlash over the service life of the screw.

Table 8

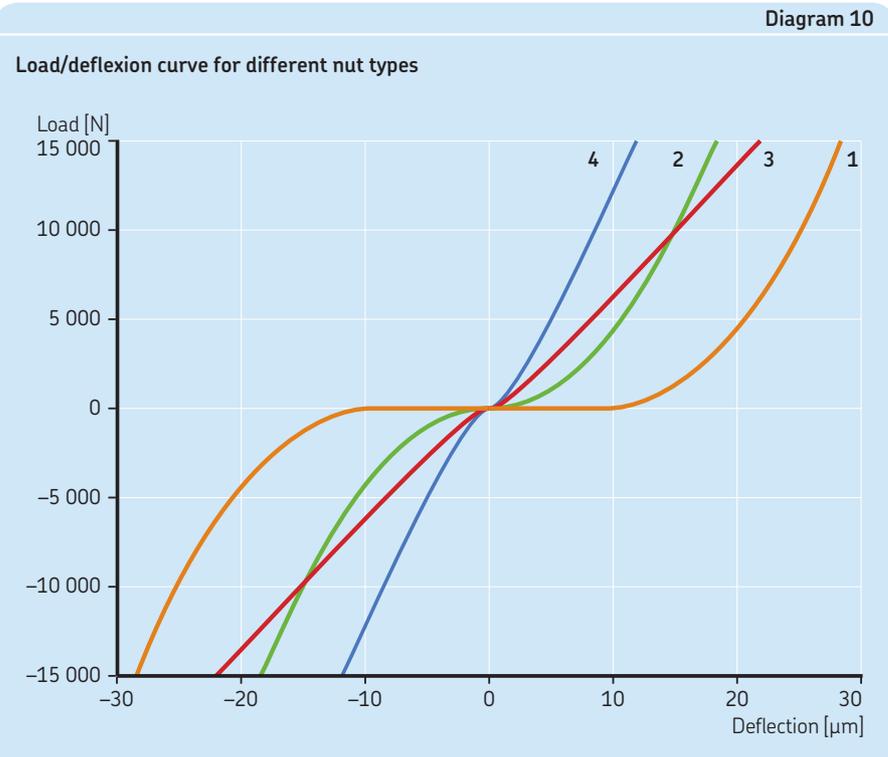

Nut type	
Prefix	Internal nut design
SR	Planetary roller screw with axial play
BR	Planetary roller screw without backlash
PR	Planetary roller screw with preloaded split nut
PRM	Planetary roller screw with preloaded double nut
SV	Recirculating roller screw with axial play
BV	Recirculating roller screw without backlash
PV	Recirculating roller screw with preloaded split nut
PVM	Recirculating roller screw with preloaded double nut

Preload and stiffness

Typical load/deflection curves for four different nut designs are shown in **diagram 10**:

- Curve #1: Single nut with axial play
- Curve #2: Single nut without backlash
- Curve #3: Preloaded split nut
- Curve #4: Preloaded double nut

Diagram 10

The effect of the internal preload in a split nut is shown in **figure 6**. A squeeze load F_q is applied to the two halves of a split nut. With a precisely ground and calibrated spacer, this squeeze load F_q generates the internal preload force F_{pr} .

The application of an external load F on a preloaded split nut results in different load values on each half of the nut (\rightarrow **fig. 7**).

The relative load distribution on the two halves of the preloaded split nut can be described by the **figure 8**:

- At point A: without external load F , the two nut halves are in equilibrium under preload F_{pr} (\rightarrow **fig. 6**)
- At point B: with external load F applied to nut half #2 (\rightarrow **fig. 7**), the axial force taken by nut half #2 increases to value F_2 , and the preload of nut half #1 is reduced to value F_1 . For all situations where $F \leq 2,83 F_{pr}$, the load seen by nut half #2 is greater than the external load. Therefore, increasing the preload would reduce the life of the screw
- At point C, where external load $F = 2,83 F_{pr}$, the axial load taken by nut half #2 is equal to F . At this point, nut half #1 becomes unloaded
- At point D, with $F = 2,83 F_{pr}$ applied to nut half #1, nut half #2 becomes unloaded.

For a given system, the level of the preload force F_{pr} corresponds to a few percentage points of its dynamic load carrying capacity C_a .

With a preloaded split nut design, the external load is taken by one of the two nut halves for a given external load direction. Under high loads, the load carrying capacity and maximum stiffness level of a preloaded split nut are substantially lower than for a one-piece nut. Under low load conditions, a preloaded split nut eliminates backlash and increases the degree of stiffness.

Fig. 6

Preload in a split nut without external load

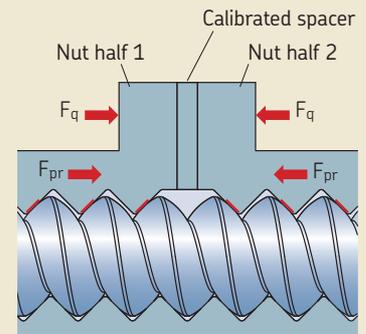

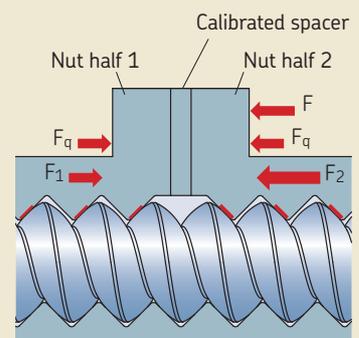

Fig. 7

Preloaded split nut with external force

Running in bench

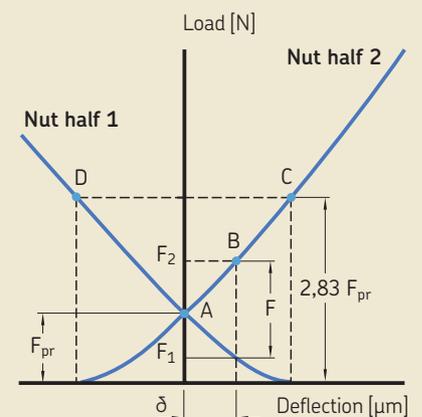

Preload torque test bench

Fig. 8

Concept of preloaded nut

Because of the very high load capacity and stiffness of roller screws, a split nut usually offers sufficient capacity for most applications and offers an extremely compact design.

In exceptional cases where the load rating of a preloaded split nut is not sufficient, two single nuts may be preloaded together (→ fig. 9). Exact dimensions are available on request by contacting SKF.

Preload torque T_{pr}

Preload torque T_{pr} is the friction torque resulting from the sole preload force F_{pr} , and is calculated considering the practical efficiency of the selected screw (see calculation formulae **pages 111 to 112**).

Preload torque tolerances

For preloaded roller screws, an optimum preload torque T_{pr} has been calculated and is provided in the product tables.

These values correspond to a compromise between the stiffness level and the preload force applied. A higher preload torque would penalize the driving torque, potentially decrease the product life and could generate additional heat, whereas a lower preload torque would decrease the level of stiffness. For specific cases where a different preload torque is required, please contact your local SKF representative.

The variation tolerance of preload torque along a screw shaft depends on:

- The helix angle of the screw thread
- The slenderness of the screw shaft (i.e. the ratio l_1/d_0 of threaded length over nominal diameter)
- The lead precision
- The preload torque range.

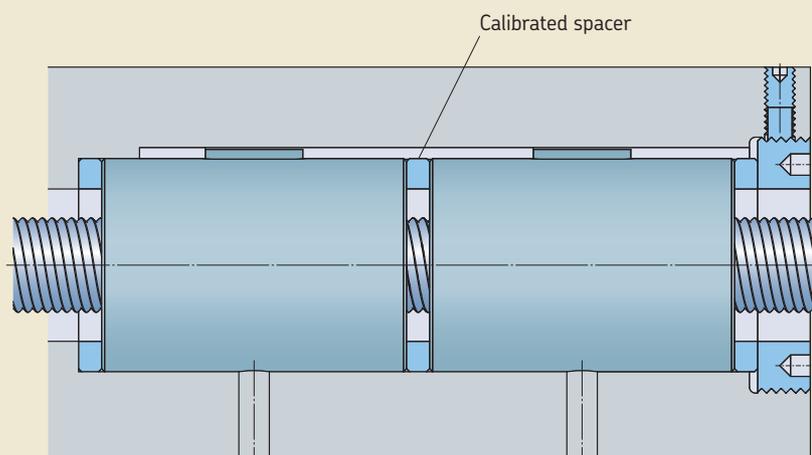

Tables 9 and 10 give the tolerances for preload torque variation, with screw thread helix angle less than 11° , and greater than 11° respectively.

Preload torque is measured at 50 r/min with ISO 68 oil grade for BR and PR screw types and with ISO 220 oil grade for BV and PV screw types.

Note:

The helix angle α can be calculated using formulae in **page 112**.

Double nut with preload

Example:

Screw PRU 39 × 5R 433/780 G3 WPR has been selected.

According to the information in the product tables, the preload torque is

$T_{pr} = 1,3 \text{ Nm}$. What is the tolerance of preload torque for G3 lead precision?

The helix angle is $2,34^\circ$ and the threaded length is 433 mm ($l_1/d_0 = 11,1 < 40$).

Table 9 gives a variation tolerance of $\pm 20\%$ for G3. All screws will exhibit a friction torque of $1,3 \text{ Nm} \pm 20\%$ or 1,04 to 1,56 Nm.

The corresponding minimum nominal nut stiffness is $R_{ng} = 750 \text{ N}/\mu\text{m}$, and the nominal reference nut stiffness is $R_{nr} = 980 \text{ N}/\mu\text{m}$.

Diagram 11 presents the above calculated ranges and a typical torque variation measurement. Preload torque or internal friction torque certificates can be supplied on request.

Preload adjustment

Cylindrical nuts

For cylindrical nuts with preload, the stoppers threaded into the housing must be tightened according to the torque values listed in **table 11** for PRU planetary roller screws (→ **fig. 12**), and in **table 12** for PVU recirculating roller screws (→ **fig. 13**).

Note that torque values in **tables 11** and **12** also apply to single piece nuts such as SRC/BRC (→ **fig. 10**) and SVC/BVC (→ **fig. 11**) nut types respectively.

Standard nuts are made of bearing steel hardened to 58 to 62 HRC. Under certain load conditions, it is necessary to use hardened and ground spacers to avoid imbedding the nut side face into the housing

shoulder and into the stopper clamping area. This precautionary measure will diminish the risk that preload and stiffness are reduced.

Flanged nuts

For flanged nuts with preload, the fixing bolts must be tightened according to the torque values listed in **table 13** for PRK planetary roller screws and PVK recirculating roller screws (→ **fig. 14**).

Lead precision and manufacturing tolerances

Lead precision

Generally speaking, the precision indicated defines the lead precision class that complies with ISO 3408-3, e.g. G1, G3 and G5 (→ **tables 14** and **15**).

Standard lead precision is G5. On request, SKF can deliver roller screws with G3 or G1 lead precision.

A roller screw lead precision class is primarily defined by the maximum permitted travel variation V_{300p} over a threaded length of 300 mm (→ **table 14**).

Lead precision characteristics are defined by the permitted lead error e_p , and the permitted travel variation V_{up} , measured at 20 °C over the useful stroke l_u (→ **tables 15, 16** and **fig. 15**).

Some customer applications require a travel compensation c to account for the effect of operating temperature on the lead precision: a temperature variation by 1 °C results in dimensional change of 11,5 $\mu\text{m}/\text{m}$ of screw shaft length. Consequently, if needed, a travel compensation c can be achieved.

- Standard case with $c = 0$ (→ **fig. 16**)
- Case with customer specific value of c (→ **fig. 17**)

Lead precision graphs can be supplied on request.

Table 16

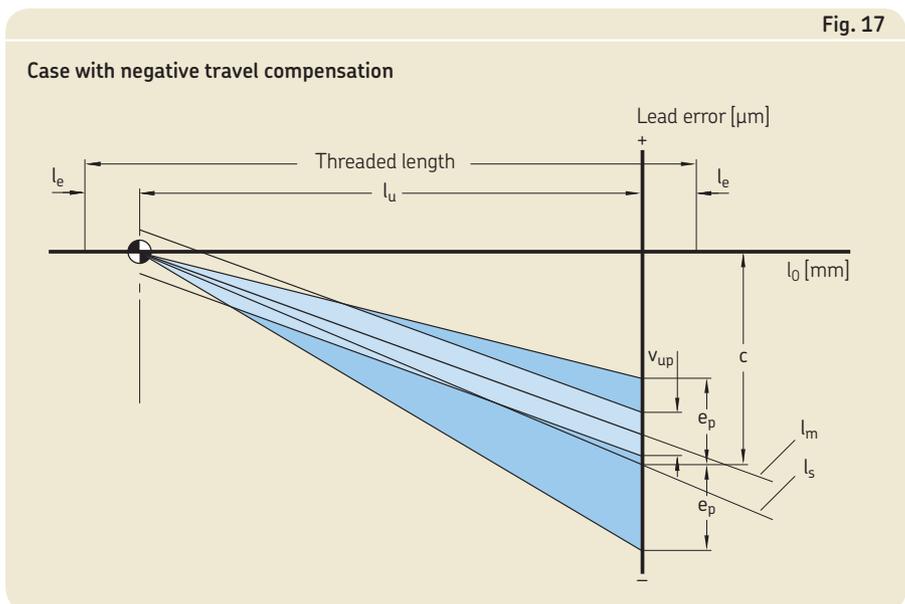

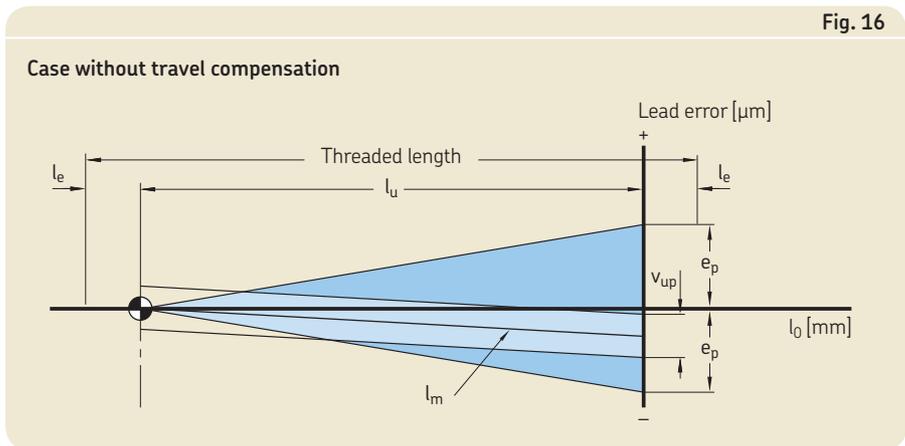

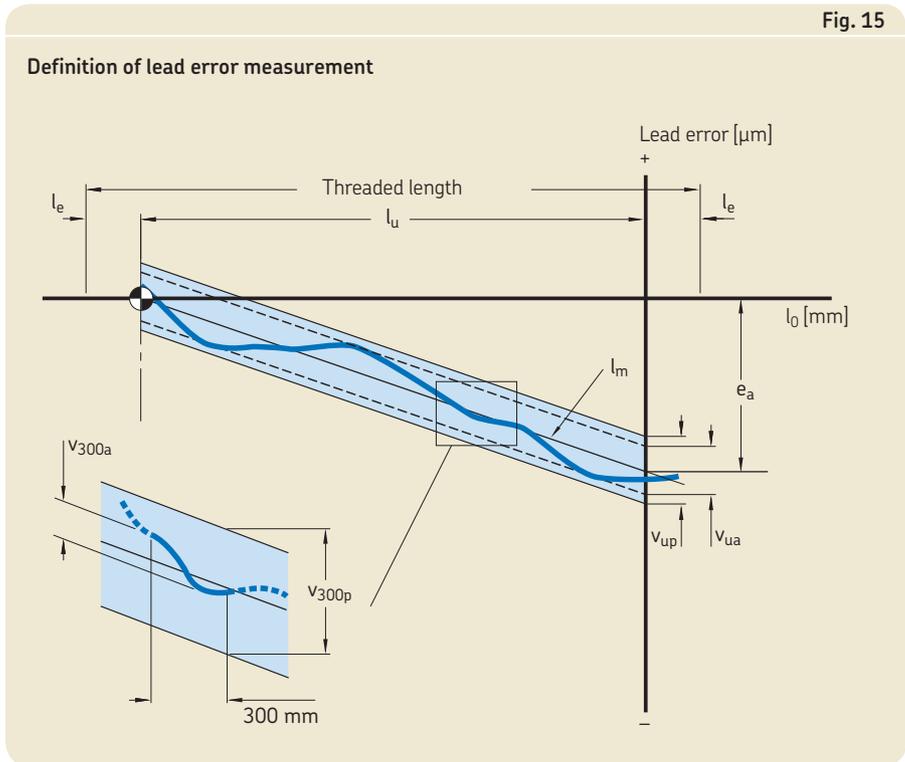

Useful travel

Type of roller screw	Useful travel $l_u = \text{threaded length} - 2 l_e$ where
Planetary roller screw	$l_e = 1 \times \text{lead}$
Recirculating roller screw	$l_e = 5 \times \text{lead}$

Symbols used in figures

l_u	useful travel
l_e	excess travel (no lead precision required)
l_m	actual mean travel (line which best fits the actual travel curve by method of least squares)
l_0	nominal travel
l_s	specified travel
c	travel compensation (difference between l_s and l_0 to be defined by the customer)
e_p	permitted mean travel deviation (lead error) over the specified travel
e_a	actual (measured) mean travel deviation over the specified travel
V	travel variation (or permissible band width)
V_{300p}	maximum permitted travel variation over 300 mm
V_{up}	maximum permitted travel variation over the useful travel l_u
V_{300a}	measured travel variation over 300 mm
V_{ua}	measured travel variation over l_u
$V_{2\pi p}$	maximum permitted travel variation within 2π rad
$V_{2\pi a}$	actual travel variation measured within 2π rad

Permissible travel variation $V_{2\pi p}$ within 2π rad (one revolution)

The maximum permissible travel variation $V_{2\pi p}$ over one revolution can be an important parameter for some very high precision applications.

This lead precision parameter $V_{2\pi p}$ is explained in **figure 18**. Values in accordance with ISO standards 3408-3 are provided in **table 17**.

On request, SKF can measure and provide the actual travel variation V_{2pa} over one revolution, for nominal screw diameters up to 40 mm and screw lengths up to 1 000 mm.

Matching of travel deviation for screws working in parallel

When 2 or more screws are used together in parallel on one piece of equipment, it's often important to match their lead deviations.

A value M is defined as the maximum difference between the mean travel of any screw in a set. In cases where three or more screws are installed, M represents the maximum difference between the two most extreme mean travels of the set of screws (→ **table 18**).

Figure 19, **figure 20** and **figure 21** represent 3 typical application examples.

Fig. 18

Travel deviation within 2π rad

a is actual travel deviation

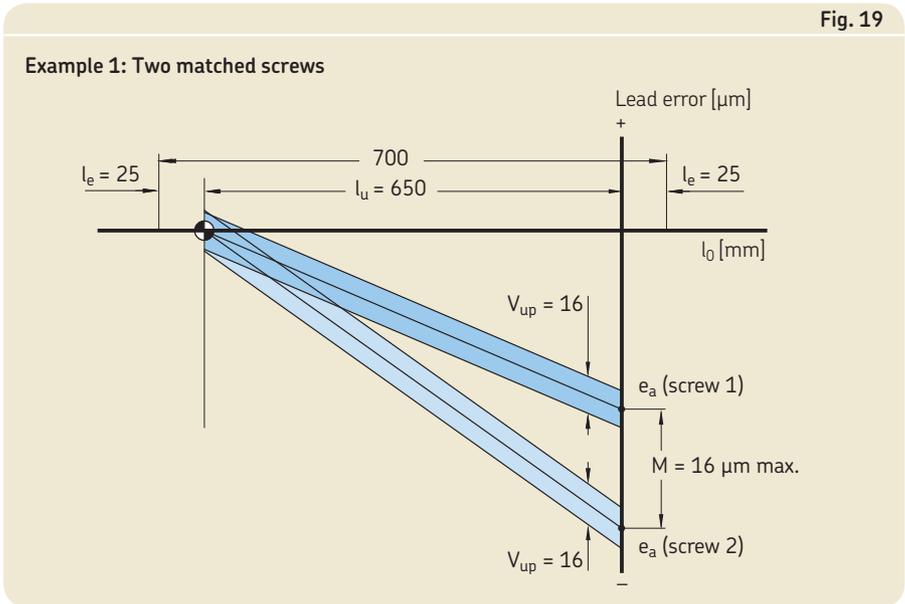

Example 1

Two planetary roller screws of type SRC 25 × 5R 700/900 G3 Z WPR with lead precision G3 are working in parallel.

$$e_p = 18 \mu\text{m}$$

$$V_{up} = 16 \mu\text{m}$$

$$M = V_{up} = 16 \mu\text{m}$$

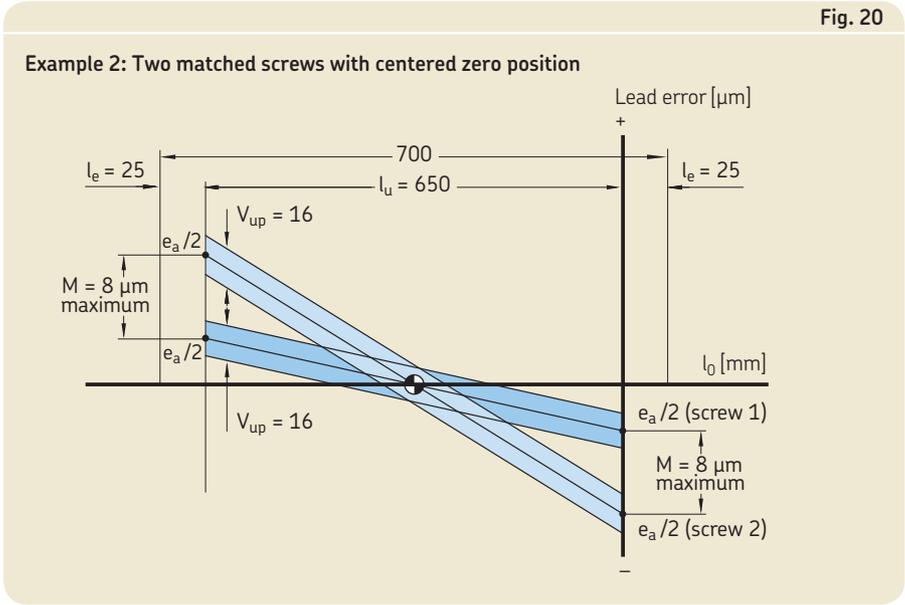

Example 2

Two planetary roller screws of type SRC 25 × 5R 700/900 G3 Z WPR with lead precision G3 are working in parallel. The zero position is regulated at the middle position of the travel of the nut.

$$e_p = 18 \mu\text{m}$$

$$V_{up} = 16 \mu\text{m}$$

$$M = V_{up} / 2 = 8 \mu\text{m}$$

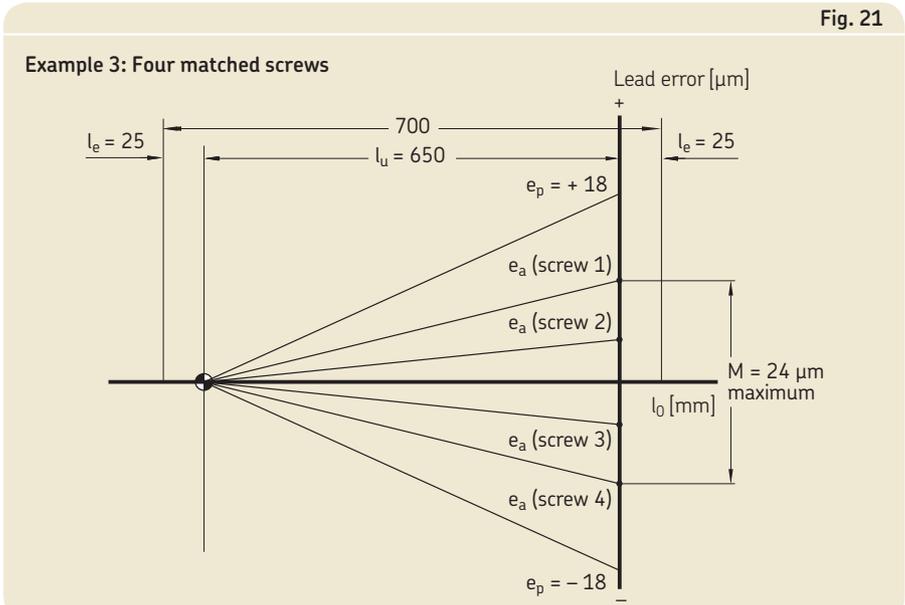

Example 3

Four planetary roller screws of type SRC 25 × 5R 700/900 G3 Z WPR with lead precision G3 are working in parallel.

$$e_p = 18 \mu\text{m}$$

$$V_{up} = 16 \mu\text{m}$$

$$M = 1,5 V_{up} = 24 \mu\text{m}$$

Manufacturing tolerances

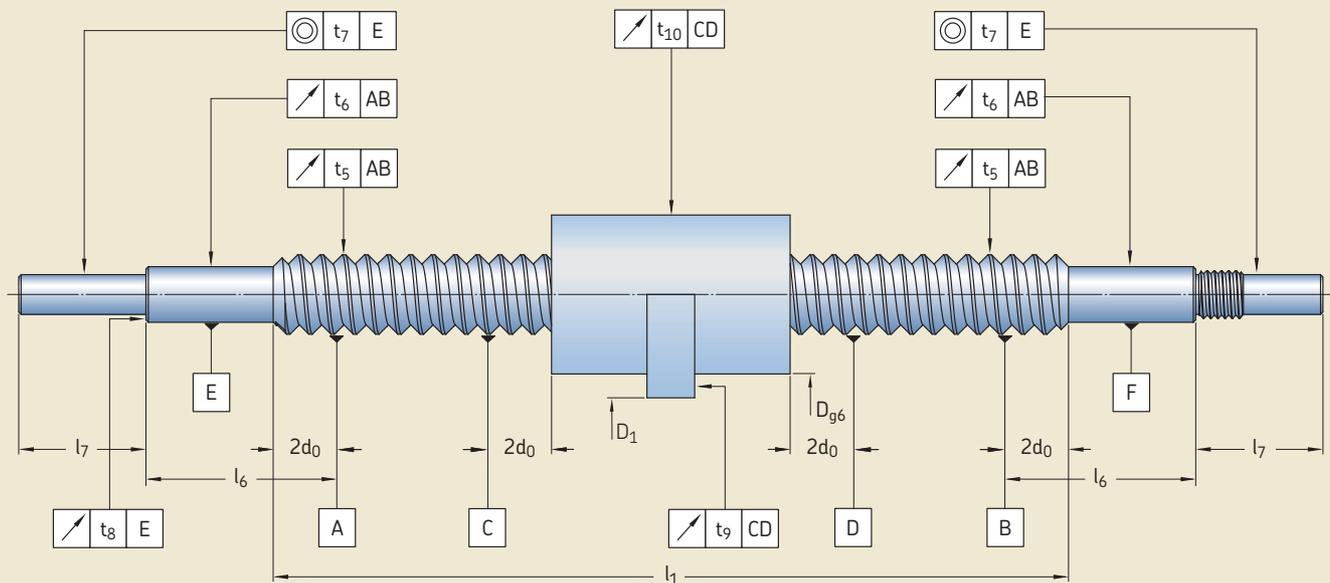

Parameters other than lead precision correspond in standard to class 5 of ISO 3408-3. If the application requires special tolerances, ISO class 3 or ISO class 1, please specify these requirements in the inquiry.

Please refer to **figure 22** and:

- **Tables 19 to 23** for manufacturing tolerances class 5
- **Tables 24 to 28** for manufacturing tolerances class 3
- **Tables 29 to 33** for manufacturing tolerances class 1

Fig. 22

Manufacturing tolerances

Shaft:

- t₅: straightness
- t₆: radial run-out of journal diameter
- t₇: concentricity of ends/journal diameter
- t₈: axial run-out of bearing support face

Nut:

- t₉: axial run-out of the nut flange face
- t₁₀: radial run-out of the nut diameter/screw

Planetary roller screws SR

Planetary roller screws operating without recirculation provide the high level of robustness, load carrying capacity, speed and acceleration, service life and reliability for ultimate driving performance.

Application examples

- Presses for plastic injection moulding and blow moulding
- Electro–mechanical presses
- Broaching machines
- Large machine tools
- Car assembly lines (spot welding, gluing, riveting, etc.)
- Factory automation
- Off–highway vehicles
- Oil & gas
- Aerospace
- Steel industry
- Test benches

Design features	User benefits
Satellite rollers without recirculation	Maximum reliability, high speed capability, low noise
Evenly spaced, guided and synchronized rollers	Robustness, resistance to shocks Very well adapted for operation with frequent changes of direction without friction torque singularities Operation within contaminated environments Smooth running
Absence of miniature parts	Very robust and durable
Nominal diameters from 8 to 120 mm	Wide standard assortment to fit most customer applications
Long leads up to 42 mm	High linear speeds up to 1,8 m/s for size 44 x 30
Small leads down to 2 mm	Ideal combination of precise positioning accuracy, increased load carrying capacity, axial stiffness, high speed and low torque requirements
Shaft length up to 8 000 mm	For additional information about longer shaft lengths, please contact your local SKF representative
Maximum $n_{d_0} = 160\,000$ Acceleration up to $12\,000\text{ rad/s}^2$ for standard SR screws, and can be higher for special variants	High speed rating of rolling screw, improving customer productivity
High dynamic load carrying capacity up to 1 131 kN for SR assortment	Long service life
High static load carrying capacity up to 4 038 kN for SR assortment	Ability to accommodate heavy shock loads without raceway damage
High axial stiffness, further increased with a preloaded version	High positioning accuracy
Roller retention for nut and shaft disassembly	Easy roller screw assembly into customer machinery, no need of sleeve like for ball screws
Optional support bearings	Complete support bearings ready to use, simplified application design and assembly, easy ordering process
Three standard versions are available: <ul style="list-style-type: none"> • SR with axial play • BR without backlash (for $d_0 \leq 64\text{ mm}$) • PR with preloaded split nut (for $d_0 \leq 64\text{ mm}$) 	Equipment stiffness and accuracy further increased with the preloaded version
On request, the SR assortment can be delivered with maximized load rating (maximum number of rollers) for sizes $d_0 \leq 80\text{ mm}$	Increased load rating within the same roller nut design
Flexible design and manufacturing equipment	Custom designs to fit customer applications, e.g. left hand threads

Ultra Power roller screws HR

The Ultra Power roller screws represent the strongest variant of the SKF planetary roller screw product line. They are designed for heavy loads and long service life.

The SKF Ultra Power assortment of planetary roller screws is optimized to provide a load carrying capacity increase up to 60% over the standard SR planetary roller screw with the same combination of diameter and lead, and, in addition, to reach the maximum possible service life within a compact space.

In order to operate within the principles of rolling fatigue and attain the L_{10} life performance, the maximum cycle operating load should not exceed 80% of the C_a value.

The maximum load should be applied on the nut flange, not on the mounting bolts.

Roller screws without backlash or with preloaded split nut are not available in this assortment.

Application examples

The Ultra Power roller screws offer the power of hydraulic actuators combined with the precision and flexibility of electric control:

- Injection moulding machines for plastic and rubber
- Electro-mechanical presses
- Broaching machines
- Large machine tools
- Off-highway vehicles
- Oil & gas equipment
- Steel industry including casting and rolling
- Friction welding
- Hydro-electric power plants
- Powerful electro-mechanical cylinders
- Heavy lifting equipment

Design features	User benefits
Planetary roller screw concept with maximized load rating	Highest possible load carrying capacity of any type of rolling screw Reliability, resistance to shock loads, robustness in harsh environments
Nominal diameters from 60 mm to 240 mm	Wide standard assortment to fit most heavy duty applications
Long leads up to 50 mm	High linear speed capability with long lead (1,2 m/s for size 112,5 × 50)
Shaft lengths up to 8 000 mm for diameters 120 and 135 mm	For additional information about longer shaft lengths, please contact your local SKF representative
Maximum $n_{d0} = 160\,000$	High speed for increased productivity
High dynamic load carrying capacity up to 3 994 kN for HR assortment	Long service life
High static load carrying capacity up to 23 350 kN for HR assortment	Ability to accommodate heavy shock loads without raceway damage
Ultra Power roller screws is available with axial play lower than 0,07 mm (0,1 mm for screws with lead ≥ 40 mm)	Unique combination of extreme load carrying capacity and driving accuracy
Standard versions include wipers (WPR in the designation). Screws can be delivered without wipers on request (designation with NOWPR suffix)	Solution contributes to long service life
Standard lead precision is G5, lead precision G3 or G1 on request	Precise driving accuracy
Optional support bearings	Wide variety of spherical roller thrust bearing combinations
Three standard versions are available: <ul style="list-style-type: none"> • HRC: cylindrical nut • HRF: nut with centered flange • HRP: nut with off-centered flange 	Increased design flexibility
Adaptable tooling for non-standard, left hand threads or special designs	Custom solutions on request. Please contact your SKF sales office for specific requirements and their feasibility

Inverted roller screws ISR

Concept

The inverted planetary roller screw provides powerful electro-mechanical actuation when compactness, low torque and high load capabilities are prerequisites.

The rollers, synchronized with the threaded shaft through toothed rings, translate along the nut. The application loads acting on the translating push tube transit through the planetary rollers to the rotating shaft or nut. Toothed rings and guides provide the rolling motion and the even circumferential position of the rollers, for near-perfect load distribution. The rings and guides also avoid any parasitic friction between the rollers.

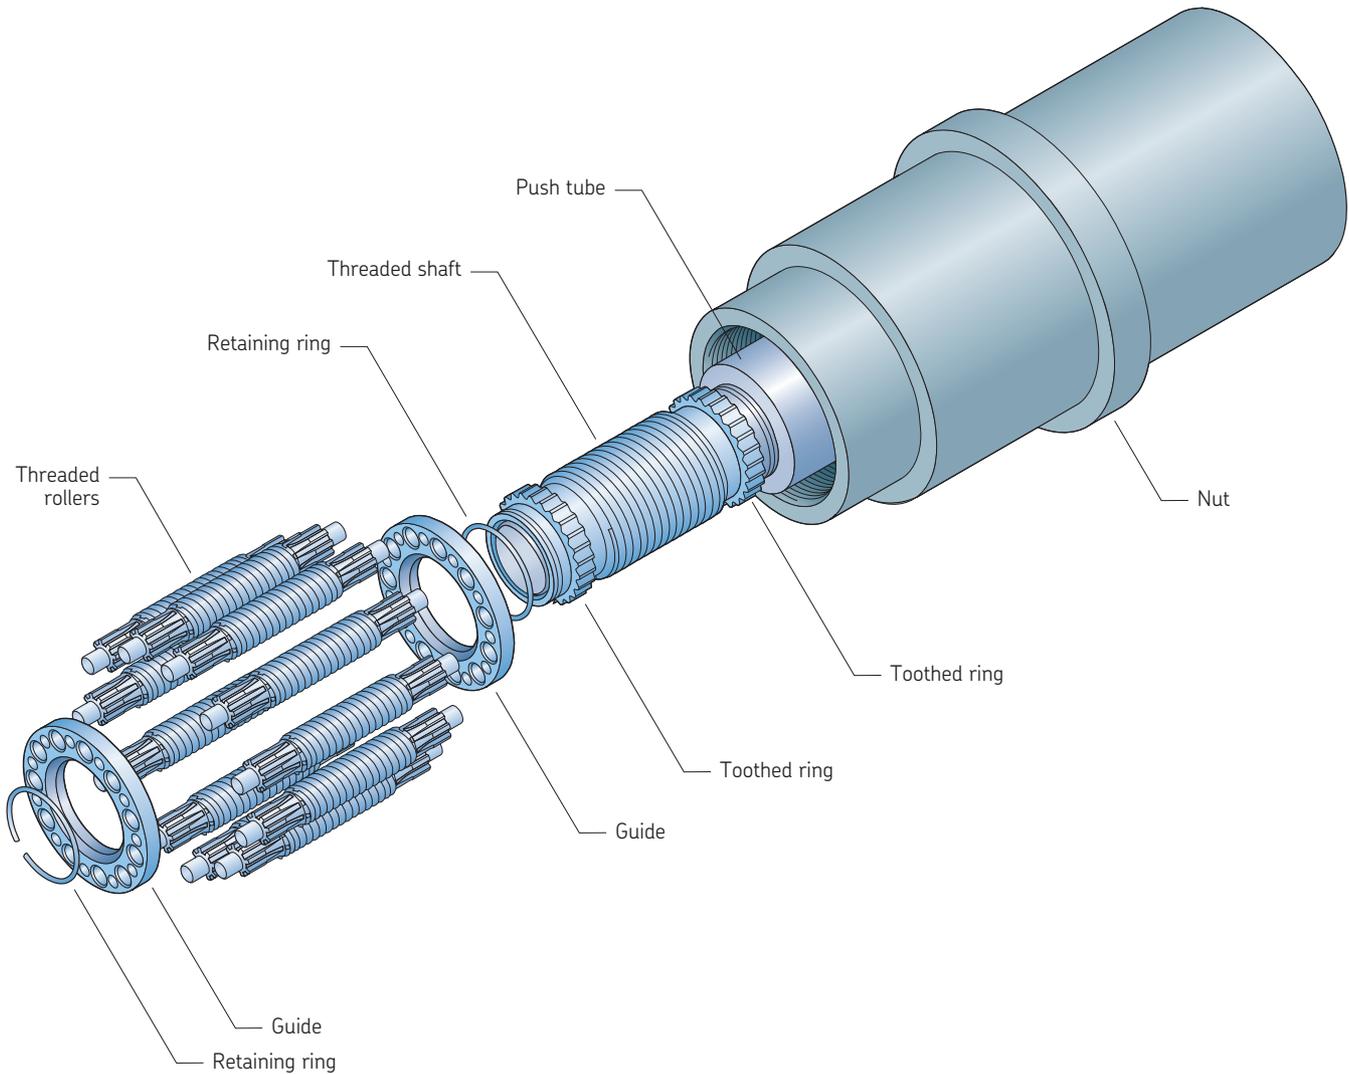

Application examples

The compact inverted roller screw, incorporated within an electro-mechanical actuator, can replace hydraulic or pneumatic actuation systems typically found in the following applications:

- Factory automation (for example, automotive assembly lines)
- Welding guns
- Portable high power tools
- Oil and gas subsea equipment
- Aerospace actuators

Design features	User benefits
Planetary roller screw concept without recirculation	Long service life and increased reliability improve productivity
Leads as small as 2,4 mm, combined with the benefits of the robust planetary roller screw design	Small leads achieved with robust threads, while providing high load carrying capacity and high axial stiffness Reduced requirements for electric motor torque to reach high load actuation
Either nut or shaft can be driven, the non-rotating and translating component acting directly as the push tube	Design flexibility Anti-rotation function can be easily integrated into the component acting as the push tube
Custom screw-to-motor attachments for easy integration	Compact, light weight solution with fewer parts for easy installation
Standard delivery without wipers	Guiding and sealing functions easily integrated on nut or shaft, resulting in high performance sealing
High speed and acceleration capability, similar to planetary roller screws	Preferred solutions for applications with high duty cycle and high cycle rates
Two versions are available: <ul style="list-style-type: none">• ISR with axial play• IBR without backlash	Equipment stiffness and accuracy further increased when backlash is eliminated
Flexible production equipment	Custom designs to fit customer applications. Multiple dimensions can be created, starting from the standard assortment of planetary roller screws
Small lead associated to a relatively large nominal nut diameter	Low backdriving ability and even self locking solutions are possible

¹⁾ Recommended maximum push tube diameter for standard inverted roller screws. For additional information about large push tube diameters, please contact your local SKF representative

²⁾ For additional information about longer strokes, please contact your local SKF representative

Rotating nut with planetary roller screws SRR

Concept

A rotating nut planetary roller screw assembly is designed to function like an electro-mechanical cylinder, and is recommended for applications where space is limited.

The basic assembly consists of a housing, two angular contact ball bearings and a roller screw nut. In the case of direct drive, a customer supplied hollow motor drives the screw nut. In the case of indirect drive, a customer supplied pulley or gear, attached to the back of the roller screw assembly is needed to drive the nut. The rotation of the nut translates the screw shaft which operates as a push tube of an electro-mechanical cylinder. The screw shaft must be fitted with an anti-rotation device and must be precisely guided.

Important:

SKF recommends that the roller screw nut be relubricated by regular injection of lubricant through an axial hole and a radial hole drilled in the roller screw shaft¹⁾.

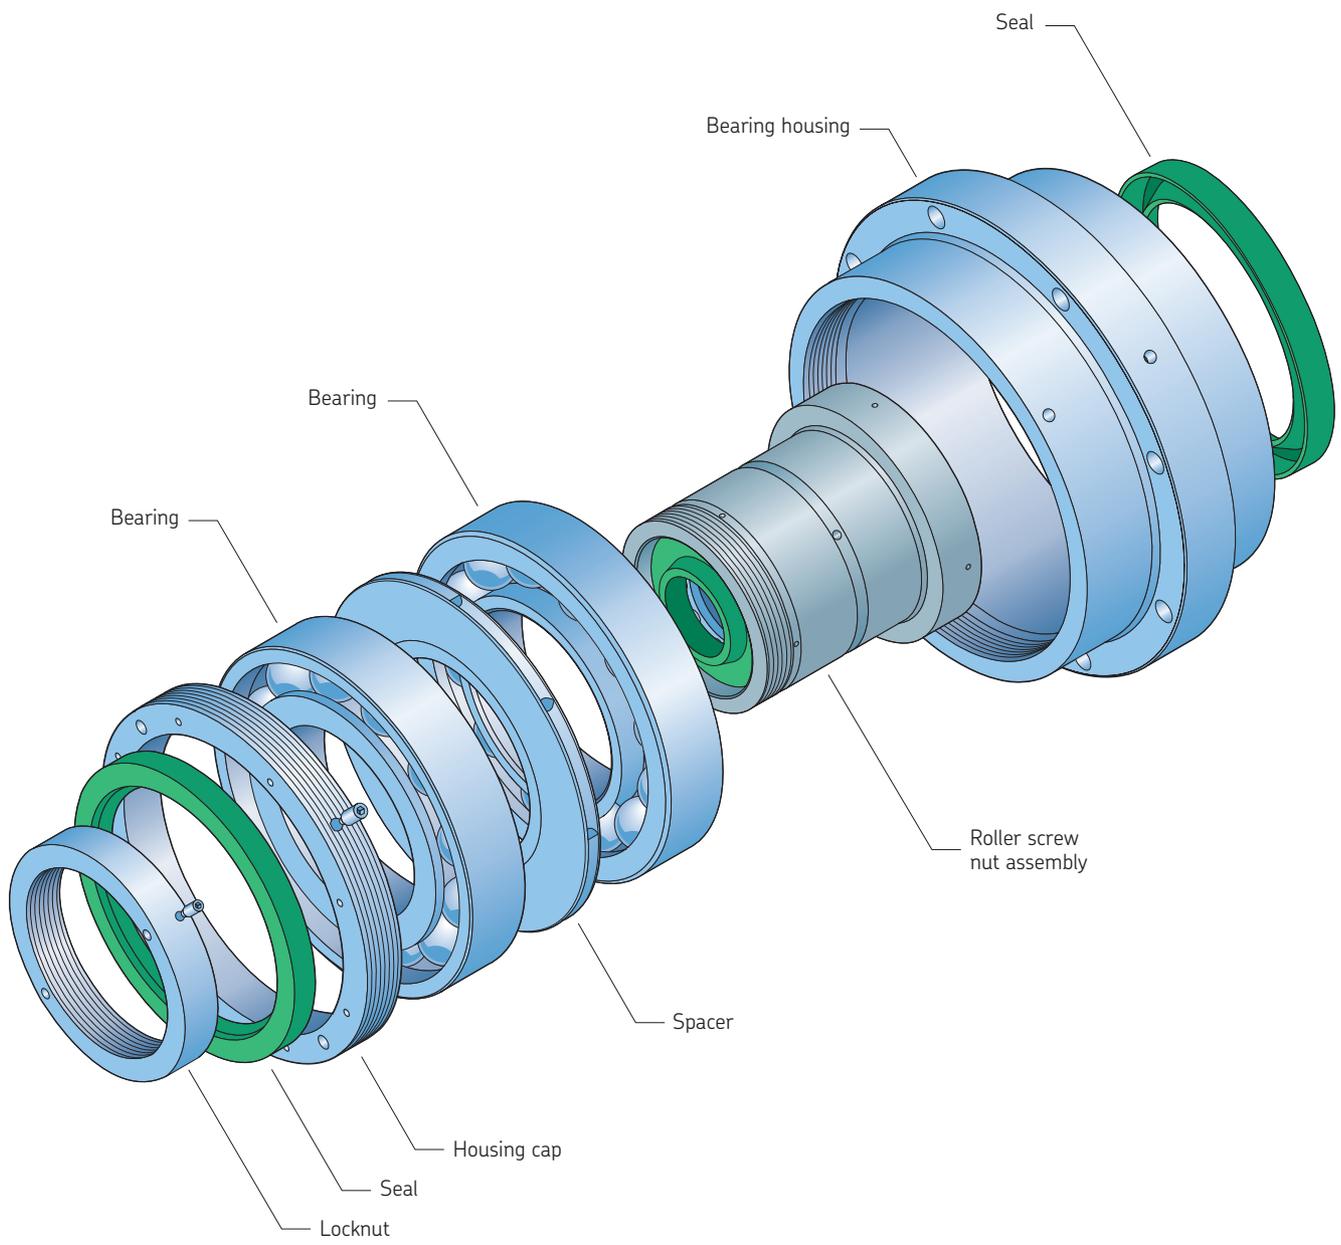

Customers are responsible for sourcing and assembling the motor and/or drive train and frame holding the bearings housing.

Application examples

- Production processes in automotive industry (servo-presses, tube bending, forming, locking devices, etc.)
- Process in the injection moulding industry (part ejection)
- Short stroke and oscillating applications

Design features	User benefits
Planetary roller screws with a nut already fitted into a bearing housing	Convenience of a roller screw and integrated support function for easy design and assembly
Maximum $n_{d0} = 160\,000$ and acceleration up to $12\,000\text{ rad/s}^2$	Ideal combination of high load carrying capacity, speed and acceleration for heavy duty applications and intensive cycling
72 series angular contact ball bearings mounted in the housing are fitted with the nut and then adjusted for preload	Length saving solution ready to incorporate into application. Simplified engineering for machine builders
Bearings in back-to-back preloaded arrangement	Robust and stiff bearing arrangement to accommodate moment loads from the power transmission
2 garter seals (2 shields for size $d_0 = 60\text{ mm}$) protect the bearings against contaminants, making these assemblies relubrication-free under normal operating conditions	Durable assembly for operation in difficult environments
Wiper seals at each end of the nut of a standard assembly help to protect the nut from contaminants	
A grease fitting for the bearings is located on the outside surface of the housing. Standard grease is SKF LGEP2. Specific grease is on request	Easy maintenance
Roller screw nut relubricated through conduits drilled in the screw shaft	Independent relubrication for the bearings and for the roller screw
Two versions are available: <ul style="list-style-type: none"> • SRR with axial play • BRR without backlash 	Stiffness and running accuracy are further improved when a roller screw without backlash is selected

¹⁾ For technical assistance regarding the roller screw nut relubrication, please contact your local SKF representative

¹⁾ Overhang of the pilot diameter for fixing the drive train of a rotating nut assembly

Recirculating roller screws SV

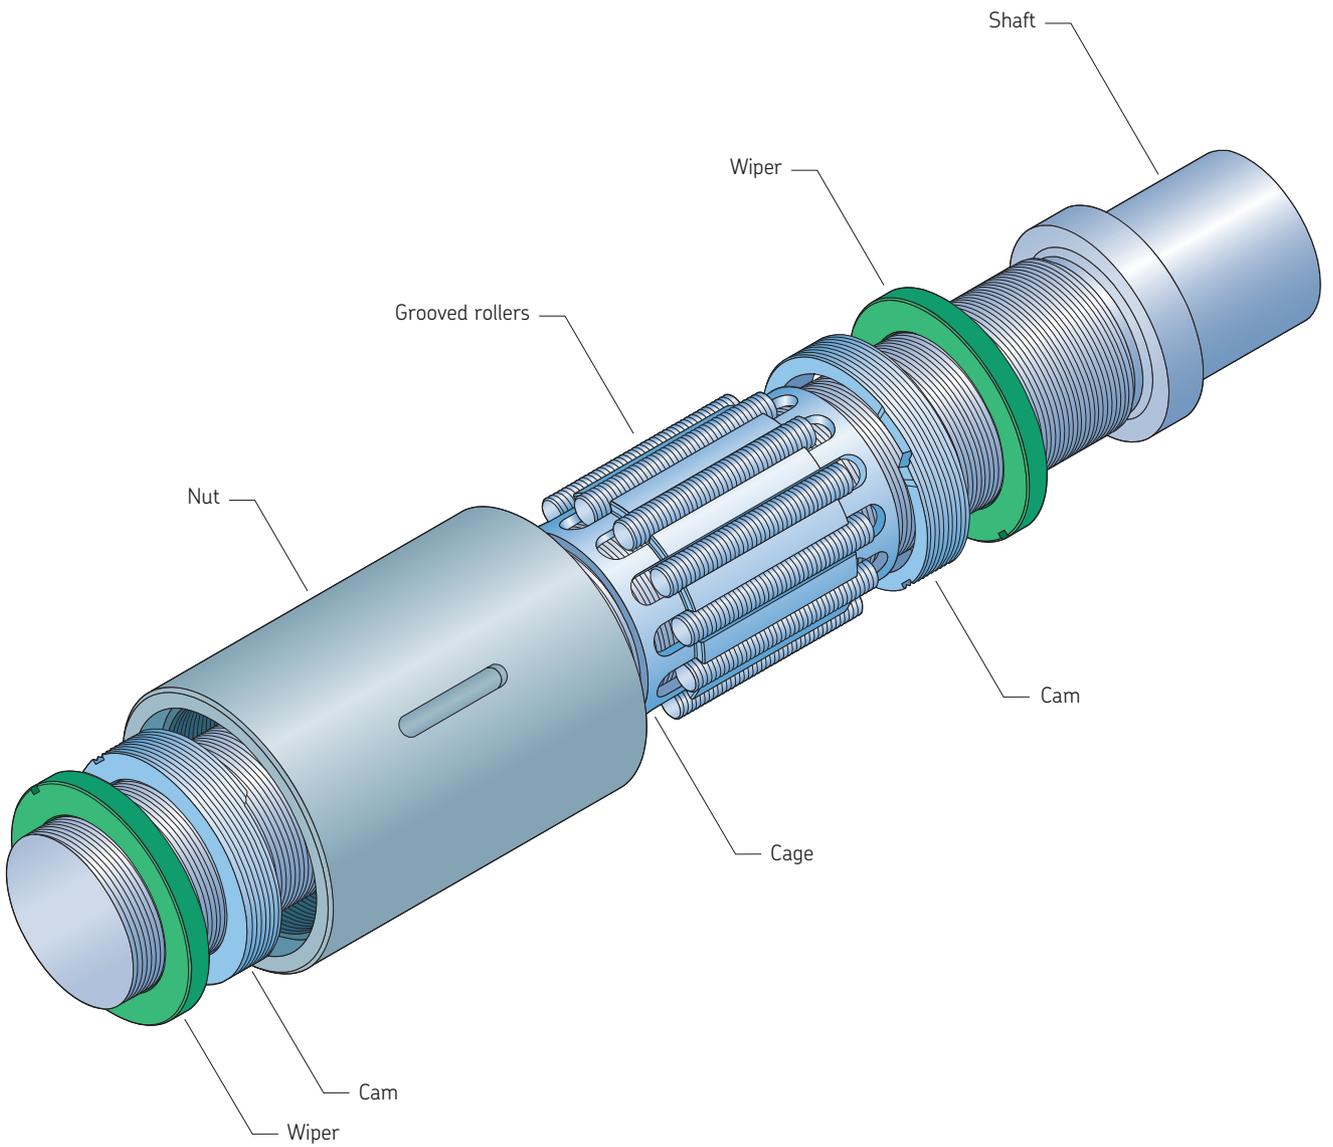

Recirculating roller screws provide the ideal combination of load carrying capacity, fine resolution, positioning accuracy and axial stiffness for ultra precision driving solutions.

The small leads and small helix angle can provide a low back-driving capability, or even self-locking ability for certain sizes of recirculating roller screws, in combination with low rolling friction.

Application examples

- Medical
- Laboratory equipment
- Semi-conductor industry
- Telescopes
- Satellites
- Precision grinders

Design features	User benefits
Absence of small parts compared to small lead ball screw	Highly robust and durable
Nominal diameters from 8 to 125 mm	Wide standard assortment to fit most applications
Standard leads from 1 mm to 5 mm	Ideal combination of precise positioning accuracy, high load carrying capacity, maximum axial stiffness, and low torque requirements Precise resolution of movement Good repeatability with small displacements
Shaft lengths up to 8 000 mm	Longer shaft lengths available on request
Maximum n $d_1 = 30\,000$ for nominal diameters $d_1 \leq 25$ mm Maximum n $d_1 = 20\,000$ for nominal diameters $d_1 > 25$ mm Accelerations up to 4 000 rad/s ²	
High dynamic load carrying capacity up to 756 kN	Long service life
High static load carrying capacity up to 2 770 kN	Ability to accommodate heavy shock loads without raceway damage
Roller retention for nut and shaft disassembly (except for diameters $d_1 < 16$ mm)	Easy roller screw assembly
Optional support bearings	Support bearings simplify design, assembly, and ordering process
Three standard versions are available: <ul style="list-style-type: none"> • SV with axial play • BV without backlash • PV with preloaded split nut 	Running accuracy and stiffness further improved without backlash or with preload
Flexible equipment	Custom designs e.g. left hand threads available on request

Support bearings FLRBU

To assist in the design and assembly process, SKF has developed a standard assortment of support bearings which consists of a housing, a bearing arrangement and seals. The bearings are adjusted at the factory to improve stiffness and running accuracy. Support bearings are filled with greased at the SKF factory and are easy to install. Standard support bearings are specifically designed for roller screws with nominal diameters from 8 mm to 80 mm (planetary roller screws) and from 8 mm to 125 mm (recirculating roller screws). These support bearings can easily be mounted on the screw shaft ends, following SKF recommendations for standard machined ends.

For larger roller screws, a preselection of spherical roller thrust bearings is also available.

FLRBU sizes 1 to 9 with angular contact ball bearings

The standard assortment of support bearings consist of a steel housing and two to six angular contact ball bearings. Support bearing size FLRBU9 is available with a total of four or six bearings (→ **pages 104 to 108**).

To attain the nominal life of the support bearings, the maximum static or dynamic operating load should not exceed 80% of the C_a value of the support bearing. This recommendation considers the load carrying capacity of the bearings, the strength of the support bearing housing and the KMT locknut.

Support bearings description

Design features

Precision machined steel housing

Preloaded SKF Explorer angular contact ball bearings, 72 or 73 series, arranged back-to-back (1 + 1 for FLRBU1 and FLRBU2, 2 + 2 for FLRBU3 to FLRBU9 and 3 + 3 for FLRBU9)

Two garter seals

Precision KMT locknut as standard

Standard screw shaft end machining defined for extremely heavy axial loads

Different bearing arrangements are available on request, should the applications present unique load conditions with the axial loads predominantly acting in one direction (1 + 3 or 3 + 1)

SKF spherical roller thrust bearings for extremely heavy axial loads

User benefits

Complete support bearing solution ready to use, simplified application design, easy ordering process
Eliminates most technical risks associated with bearing and seal assemblies

Bearing solutions offering high speed capability and low friction torque
Bearings are arranged back-to-back and preloaded to increase stiffness and improve running accuracy

Greased for life

KMT locknuts are part of the standard SKF product assortment, and can be ordered separately

Quick connection to shaft ends

Bearing load carrying capacity matched to the roller screw load carrying capacity and application conditions

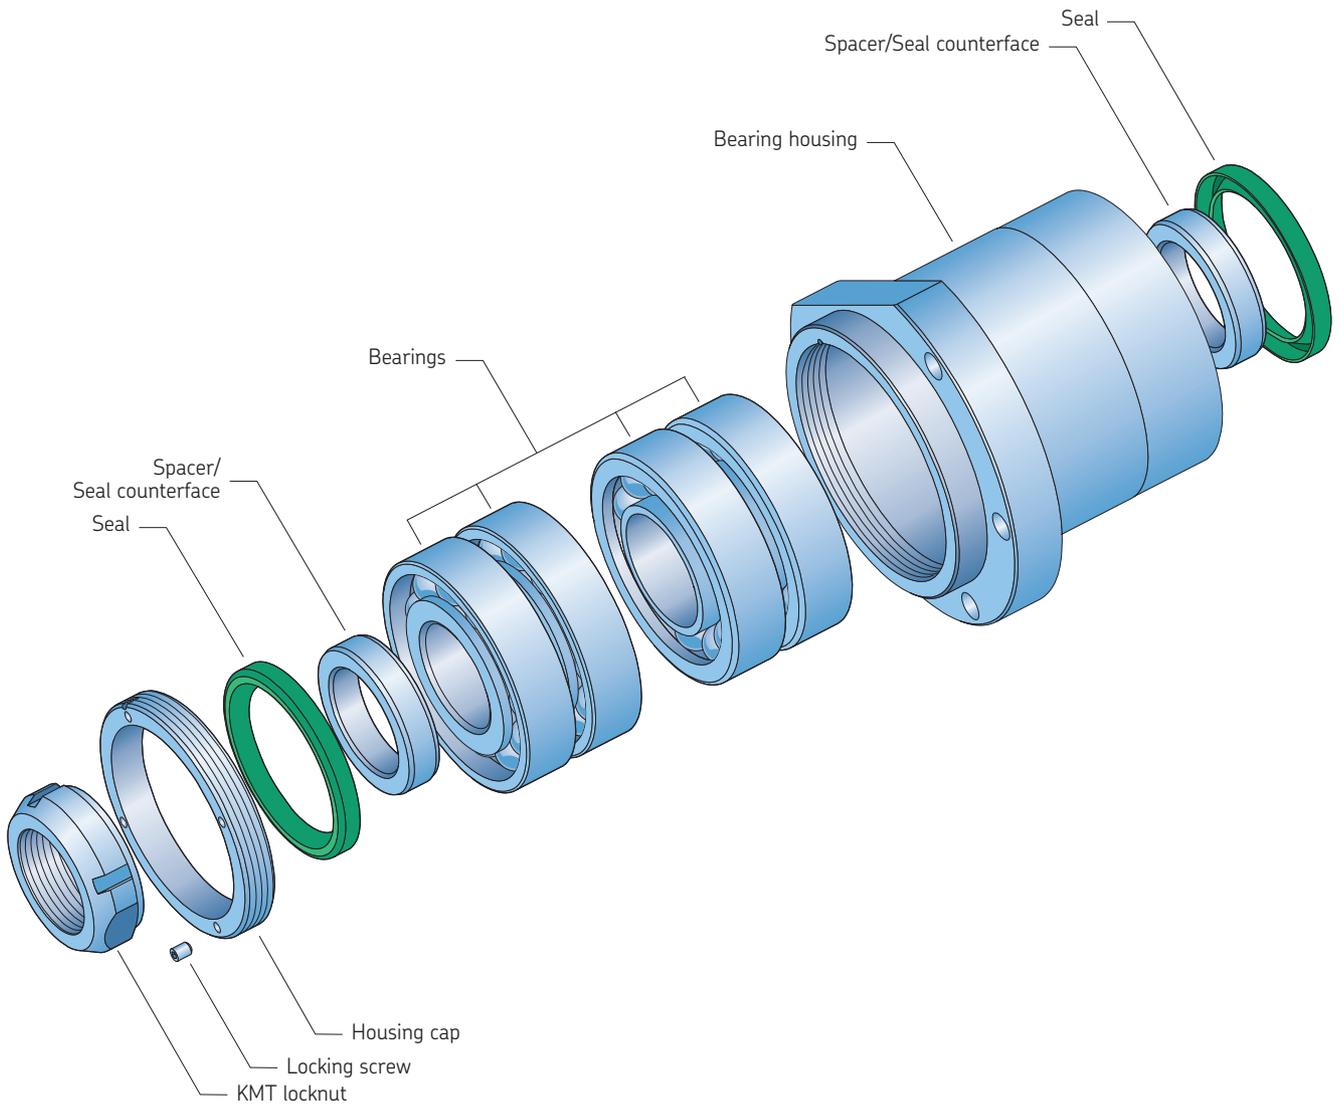

Support bearing dimensioning and load carrying capacity matched to the roller screw characteristics

Larger support bearing sizes with spherical roller thrust bearings

For extremely high load applications, SKF has preselected sizes of spherical roller thrust bearings for assembly with back-to-back arrangement into larger support bearings. These support bearings are typically used in applications where there are extremely heavy axial loads in one direction

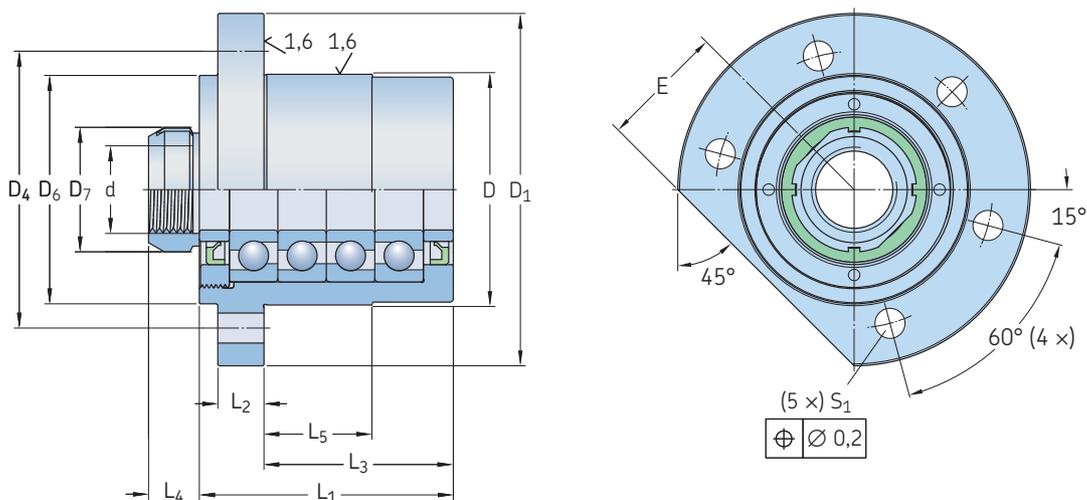

and lighter loads in the other direction, e.g. presses. As a result, these assemblies typically have two different size bearings, supporting the application axial loads in each direction, and requiring the support bearing to be oriented correctly (→ **fig. 24, page 109**).

For additional information about optimizing the selection of each spherical roller thrust bearing, please contact your local SKF representative.

¹⁾ Standard tolerance for direct drive: d_4 h6. Recommended tolerance for parallel drive: d_4 k6

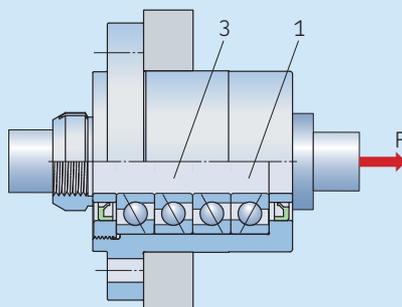

Recommendations for support bearings assembly and orientation

Standard support bearing orientation: Flange oriented towards machined end of shaft

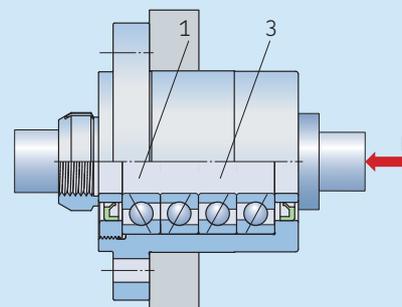

FLRBU (1 + 1) (2 + 2) (3 + 3)

- Assembly recommended for similar tension and compression loads on roller screw
- Customer to check flange fixing bolts with compression loads

FLRBU (3 + 1)

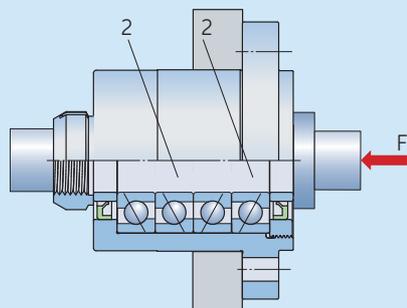

- Assembly recommended for predominantly tension loads on roller screw
- Customer to check flange fixing bolts with compression loads

FLRBU (1 + 3)

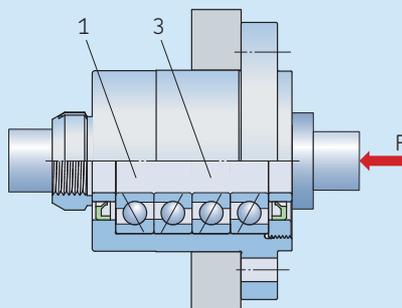

- Not the ideal assembly in case of predominantly compression loads on roller screw
- Customer to check flange fixing bolts with compression loads

Non-standard support bearing orientation: Flange oriented towards thread of roller screw shaft

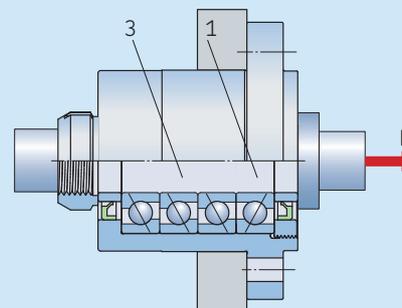

FLRBU (1 + 1) (2 + 2) (3 + 3)

- Assembly recommended for similar tension and compression loads on roller screw
- Customer to check flange fixing bolts with tension loads

FLRBU (3 + 1)

- Assembly recommended for predominantly compression loads on roller screw
- Customer to check flange fixing bolts with tension loads

FLRBU (1 + 3)

- Not the ideal assembly in case of predominantly tension loads on roller screw
- Customer to check flange fixing bolts with tension loads

Preselection of spherical roller thrust bearings

Fig. 23

Symmetrical bearing arrangement

Fig. 24

Non-symmetrical bearing arrangement

For applications where FLRBU9 support bearings cannot accommodate existing loads, SKF can supply FLRBUs containing spherical roller thrust bearings. These larger support bearings complement the assortment of large roller screws and Ultra Power roller screws.

Spherical roller thrust bearing arrangements can be either symmetrical or non-symmetrical. Non-symmetrical arrangements are typically used when loads are heavier on one direction than the other.

Because these support bearings are used on large machinery, SKF designs the housing and bearing arrangement on a case by case basis.

For additional information about these support bearings, please contact your local SKF representative.

B.6

¹⁾ SKF Explorer bearing

For selection and dimensioning of spherical roller thrust bearings, for recommendations regarding minimum load, calculation of equivalent dynamic/static bearing loads, lubrication, design of bearing arrangements and mounting, please refer to SKF catalogue *Rolling bearings*.

In particular, the following calculation assumptions must be used:

- The maximum axial load must not exceed a quarter of the bearing static load rating

$$s_0 = C_0/F$$

$$s_0 \geq 4$$

With

C_0 = bearing static load carrying capacity [kN]

F = maximum static or dynamic axial load applied to the roller screw and to the bearing carrying this load [kN]

- The permissible rotational speed of the bearing depends on the ratio of dynamic load rating to bearing equivalent mean load F_m

If $C/F_m \leq 4$
 → Maximum $n_{d_m} = 60\,000$

With $C/F_m = 8$
 → Maximum $n_{d_m} = 120\,000$

If $C/F_m \geq 15$
 → Maximum $n_{d_m} = 200\,000$

With

C = bearing dynamic load carrying capacity [kN] according to the SKF catalogue *Rolling bearings*

F_m = equivalent dynamic load applied to the roller screw and to the spherical roller thrust bearing carrying this axial load [kN]

n = screw shaft rotational speed [r/min]

d_m = bearing mean diameter [mm]

Calculation formulae and example

Calculation formulae

Basic life rating

$$L_{10} = \left(\frac{C_a}{F_m} \right)^3$$

Required load rating

$$C_{req} = F_m (L_{10 req})^{1/3}$$

where

- L_{10} = basic rating life [million revolutions]
- C_a = basic dynamic load rating [N]
- C_{req} = required dynamic load rating [N]
- F_m = cubic mean load [N]
- $L_{10 req}$ = required life [million revolutions]

Equivalent mean load

- Duty cycle with step loading

$$F_m = \left(\frac{\sum F_i^3 l_i}{\sum l_i} \right)^{1/3}$$

where

- l_i = length of stroke segment i
- F_i = load during stroke i
- F_i can be either a fixed value, or a calculation for continuous load varying cycles

- Duty cycle with continuous load variation

$$F_m = \frac{F_{min} + 2 F_{max}}{3}$$

where

- F_{min} = minimum load
- F_{max} = maximum load

Critical speed of screw shaft (no safety factor)

$$n_{cr} = 49 \times 10^6 \frac{f_1 d_2}{l_{cr}}$$

where

- n_{cr} = critical speed [r/min]
- d_2 = screw shaft root diameter [mm]
- l_{cr} = free length, or distance between the two supports [mm]
- f_1 = mounting factor
- 0,9 ●● fixed, free (→ fig. 25)
- 2,5 ●● radial support, radial support (→ fig. 26)
- 3,8 ●● fixed, radial support (→ fig. 27)
- 5,6 ●● fixed, fixed (→ fig. 28)

Notes:

- For each particular application, the most unfavorable conditions must be considered
- It is generally recommended to apply a safety factor of 0,8 to the calculated value of the critical speed n_{cr} of the screw shaft.

Speed limit of the mechanism (maximal speed applied through very short periods)

$n_{d0} \leq 160\,000$ for all types of planetary roller screws

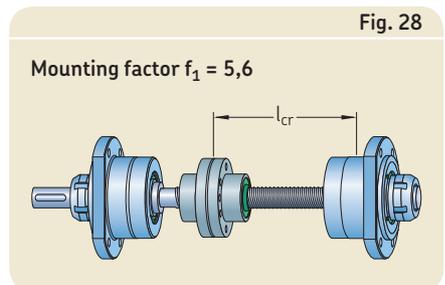

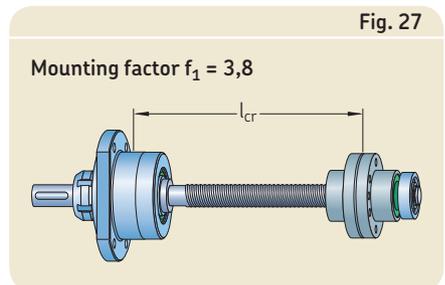

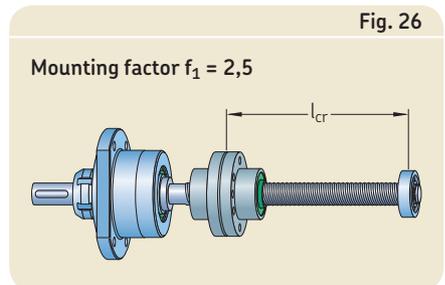

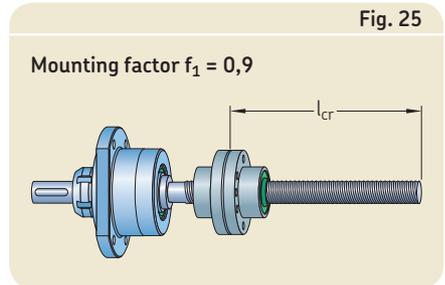

$n_{d1} \leq 30\,000$ for SV, BV, PV with $d_1 \leq 25$ mm

$n_{d1} \leq 20\,000$ for SV, BV, PV with $d_1 > 25$ mm

where

- n = rotational speed [r/min]
- d_0 = screw shaft nominal diameter for all types of planetary roller screws [mm]
- d_1 = screw shaft nominal diameter for recirculating roller screws [mm]

Maximum permissible acceleration:
 12 000 rad/s² for all types of planetary roller screws
 4 000 rad/s² for all types of recirculating roller screws

Buckling strength with safety factor 3

$$F_c = \frac{34 \times 10^3 f_3 d_2^4}{l_{fc}^2}$$

where

F_c = buckling strength [N]

d_2 = screw shaft root diameter [mm]

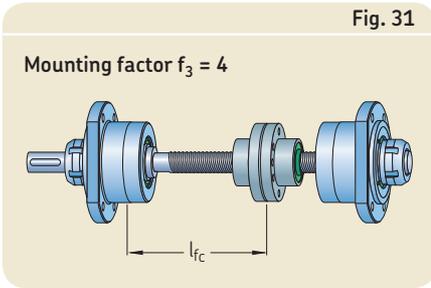

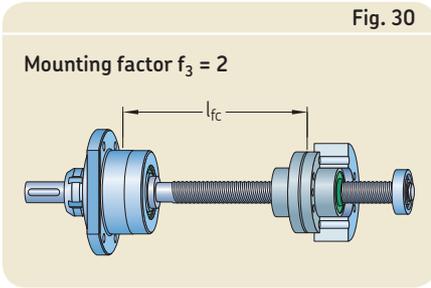

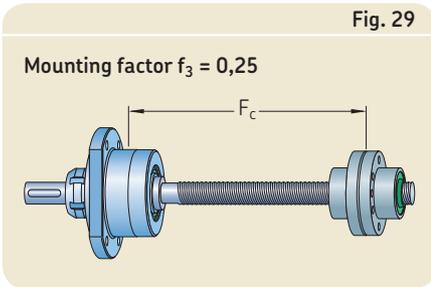

l_{fc} = distance between the fixed support bearing and the extended position of the nut [mm]

f_3 = mounting factor

0,25 ●● — fixed, free (→ fig. 29)

2 ●● —● fixed, radial support (→ fig. 30)

4 ●● —●● fixed, fixed (→ fig. 31)

Helix angle

$$\alpha = \text{Atan}\left(\frac{P_h}{\pi d}\right)$$

where

d = nominal diameter of screw shaft [mm]

- d_0 for SR planetary roller screws
- d_1 for SV recirculating roller screws
- D_0 for ISR inverted roller screws

P_h = lead [mm]

Theoretical efficiencies

Direct (→ diagram 2, page 22)

$$\eta = \frac{1}{1 + \frac{\pi d}{P_h} \mu_{ref}}$$

where

μ_{ref} is extracted from the coefficient of friction diagram (→ diagram 1 page 22)

α = helix angle [°]

d = nominal diameter of screw shaft [mm]

- d_0 for SR planetary roller screws
- d_1 for SV recirculating roller screws
- D_0 for ISR inverted roller screws

P_h = lead [mm]

Indirect (→ diagram 3, page 22)

$$\eta' = 2 - \frac{1}{\eta}$$

Practical efficiencies

Direct (→ diagram 2, page 22)

$$\eta_p = \frac{1}{1 + \frac{\pi d}{P_h} \mu_{prac}}$$

where

μ_{prac} is extracted from the coefficient of friction diagram (→ diagram 1, page 22)

α = helix angle [°]

d = nominal diameter of screw shaft [mm]

- d_0 for SR planetary roller screws
- d_1 for SV recirculating roller screws
- D_0 for ISR inverted roller screws

P_h = lead [mm]

Indirect (→ diagram 3, page 22)

$$\eta'_p = 2 - \frac{1}{\eta_p}$$

Input torque in a steady state

$$T = \frac{F P_h}{2000 \pi \eta_p}$$

where

T = input torque [Nm]

F = external load [N]

P_h = lead [mm]

η_p = practical direct efficiency

Power requirement in a steady state

$$P = \frac{F n P_h}{60000 \eta_p}$$

where

P = power required [W]

n = revolutions per minute [r/min]

Preload torque

$$T_{pr} = \frac{F_{pr} P_h}{1000 \pi} \left(\frac{1}{\eta_p} - 1 \right)$$

where

T_{pr} = preload torque [N]

F_{pr} = preload force [N]

Braking torque (the restraining torque considered in a back-driving system)

$$T_b = \frac{F P_h \eta'}{2000 \pi}$$

where

T_b = braking torque [Nm]

F = external load [N]

To consider the worst case conditions, use the theoretical indirect efficiency.

Nominal motor torque during acceleration

For a horizontal screw

$$T_t = T_f + T_{pr} + \frac{P_h (F + m_L \mu_f g)}{2\,000 \pi \eta_p} + \dot{\omega} \Sigma I$$

For a vertical screw

$$T_t = T_f + T_{pr} + \frac{P_h (F + m_L g)}{2\,000 \pi \eta_p} + \dot{\omega} \Sigma I$$

where

T_t = driving torque [Nm]

T_f = friction torque in support bearings, motors, seals, etc... [Nm]

T_{pr} = preload torque [Nm]

μ_f = coefficient of friction of guidance systems

$\dot{\omega}$ = angular acceleration [rad/s²]

m_L = mass in movement [kg]

g = acceleration of gravity [9,8 m/s²]

ΣI = $I_M + I_L + I_S \mid 10^{-9}$

where

$$I_L = m_L \left(\frac{P_h}{2\pi} \right)^2 10^{-6}$$

where

I_M = inertia of motor [kgm²]

I_S = inertia of screw shaft per meter [kgmm²/m]

l = length of screw shaft [mm]

For a hollow shaft, the actual inertia is calculated as follows:

$$I_{S \text{ actual}} = I_S \mid 10^{-9} \left(\frac{d_0^4 - d_b^4}{d_0^4} \right)$$

where

d_b = bore diameter of the shaft [mm]

Nominal braking torque during deceleration

For a horizontal screw

$$T'_b = \frac{P_h \eta' [F + m_L \mu_f g]}{2\,000 \pi} + \dot{\omega} \Sigma I - T_f - T_{pr}$$

For a vertical screw

$$T'_b = \frac{P_h \eta' [F + m_L g]}{2\,000 \pi} + \dot{\omega} \Sigma I - T_f - T_{pr}$$

where

T'_b = braking torque during deceleration [Nm]

Static axial stiffness of a complete roller screw assembly

$$\frac{1}{R_t} = \frac{1}{R_s} + \frac{1}{R_n} + \frac{1}{R_p}$$

where

R_t = stiffness of a complete assembly [N/μm]

R_s = shaft stiffness [N/μm]

R_n = nut stiffness [N/μm]

R_p = support bearings stiffness [N/μm]

Shaft stiffness

Fixed-free or fixed-radial support

$$R_s = 165 \frac{d_2^2}{l_{s1}} \quad (\rightarrow \text{fig. 32})$$

Fixed-fixed assembly

$$R_s = \frac{165 d_2^2 l_s}{l_{s1} (l_s - l_{s1})} \quad (\rightarrow \text{fig. 33})$$

Note:

The lowest stiffness is reached when the nut is in central position

$$l_{s1} = \frac{l_s}{2} \Rightarrow R_s = \frac{165 d_2^2}{l_s} \times 4$$

where

l_{s1} = distance between center of fixed support bearing and center of nut [mm]

l_s = distance between centers of fixed support bearings

For additional information, please contact your local SKF representative.

Fig. 32

Configuration with fixed support and radial support for stiffness calculation

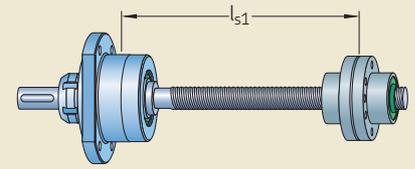

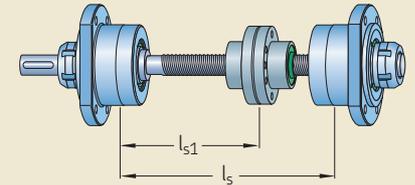

Fig. 33

Configuration with two fixed supports for stiffness calculation

Calculation example

- Customer wishes to select a planetary roller screw for his application
- To achieve the required linear speed of the application, customer has preselected a lead of 20 mm. Screw rotational speed is 600 r/min during the operation cycle
- Nut type should be flanged for assembly purposes
- Roller screw shaft is horizontally mounted, with one fixed end on the start position, and the other end on radial support
- Load cycle is shown in **diagram 12**
- Operation is 1 cycle/minute, 7 hours/day, 260 days /year for 5 years minimum

Calculation of equivalent mean load F_m

$$F_1 = 50\,000 \text{ N} \quad \text{on } L_1 = 1\,500 \text{ mm}$$

$$F_{2m} = \frac{2F_1 + F_2}{3} = 45\,833 \text{ N} \quad \text{on } L_2 = 1\,000 \text{ mm}$$

$$F_3 = 37\,500 \text{ N} \quad \text{on } L_3 = 1\,250 \text{ mm}$$

$$F_4 = 20\,000 \text{ N} \quad \text{on } L_4 = 1\,250 \text{ mm}$$

$$F_m = \sqrt[3]{\frac{50\,000^3 \times 1\,500 + 45\,833^3 \times 1\,000 + 37\,500^3 \times 1\,250 + 20\,000^3 \times 1\,250}{1\,500 + 1\,000 + 1\,250 + 1\,250}}$$

$$F_m = 41\,590 \text{ N}$$

Calculation of required dynamic carrying capacity $C_{a \text{ req}}$

With consideration to the operational cycle:

With the preselection of lead $P_h = 20 \text{ mm}$

$$\text{Minimum } L_{10} = 60 \times 7 \times 260 \times 5 = 546\,000 \text{ cycles}$$

$$L_{10} = 546\,000 \frac{1\,500 + 1\,000 + 1\,250 + 1\,250}{20} = 136,5 \times 10^6 \text{ revolutions}$$

$$C_{a \text{ req}} = F_m (L_{10})^{1/3} = 41\,590 (136,5 \times 10^6)^{1/3} = 214\,141 \text{ N}$$

Looking at the product tables, we find that:

SRF 48 × 20R with $C_a = 265\,690 \text{ N}$ satisfies the requirement of minimum dynamic carrying capacity

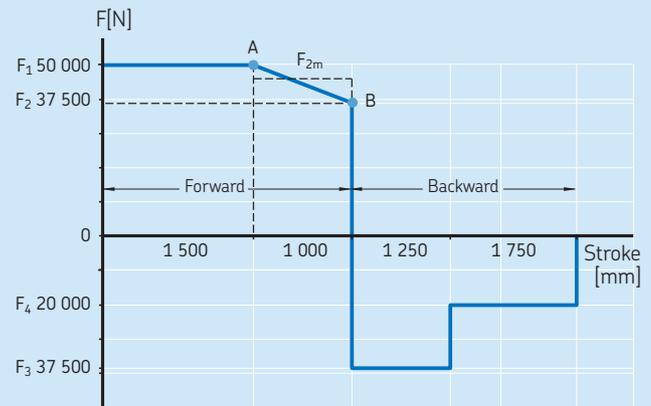

Selection of support bearing

The table on **page 107** indicates that support bearing size FLRBU7 is recommended for screw type SRF 48 × 20R.

In the following calculations, we will assume that the radial support at the other end of the screw shaft has a total width of 50 mm.

Diagram 12

Application load cycle

Efficiencies

Theoretical direct efficiency

$$\alpha = \text{Atan} \left(\frac{P_h}{\pi d_0} \right) = 7,55^\circ$$

Taken from the coefficient of friction reference diagram (→ **diagram 1 page 22**)

where

$$\mu_{\text{ref}} = 0,016$$

$$\mu_{\text{prac}} = 0,021$$

$$\eta = \frac{1}{1 + \frac{\pi d_0}{P_h} \mu_{\text{ref}}} = 0,892$$

Theoretical indirect efficiency

$$\eta' = 2 - \frac{1}{\eta} = 0,879$$

Practical direct efficiency

We consider the practical coefficient of friction $\mu_{\text{prac}} = 0,021$

$$\eta_p = \frac{1}{1 + \frac{\pi d_0 \mu_{\text{prac}}}{P_h}} = 0,863$$

Input torque in a steady state

Phase 1 has the highest application load $F_{\text{max}} = 50\,000\text{ N}$

$$T = \frac{F P_h}{2\,000 \pi \eta_p} = \frac{50\,000 \times 20}{2\,000 \pi \times 0,863} = 184,4\text{ Nm}$$

Power requirement in a steady state

Phase 1 has the highest application load $F_{\text{max}} = 50\,000\text{ N}$

Rotational speed is 600 r/min

$$P = \frac{50\,000 \times 600 \times 20}{60\,000 \times 0,863} = 11\,587\text{ W}$$

Braking torque

Phase 1 has the highest application load $F_{\text{max}} = 50\,000\text{ N}$

$$T_b = \frac{50\,000 \times 20 \times 0,879}{2\,000 \pi} = 139,9\text{ Nm}$$

Critical speed of screw shaft

For the critical speed evaluation, we have to consider the most critical configurations for the screw, where we encounter the longest shaft free length. In the present case study, the two most critical configurations are:

A) Nut at start position (zero stroke) that gives a free length of 2 608,5 mm between the center of the nut and the center of the radial support at the end of the shaft (→ **page 116** and **fig. 34**).

In this configuration, the mounting conditions are supported/supported with a corresponding factor $f_1 = 2,5$

The root diameter $d_2 = 45,5\text{ mm}$, the calculated critical speed is:

$$n_{\text{cr}} = 49 \times 10^6 \frac{2,5 \times 45,5}{2\,608,5^2} = 819\text{ r/min}$$

By applied a safety factor of 0,8:

$$n_{\text{cr}} \times 0,8 = 819 \times 0,8 = 655\text{ r/min} > 600\text{ r/min} \Rightarrow \text{Ok}$$

B) Nut at full stroke of 2 500 mm that gives a free length of 2 719,5 mm between the center of the nut and the center of the fixed support bearing (→ **page 116**, **fig. 35**).

In this configuration, the mounting conditions are fixed/supported with corresponding factor $f_1 = 3,8$

The calculation is:

$$n_{\text{cr}} = 49 \times 10^6 \frac{3,8 \times 45,5}{2\,719,5^2} = 1\,146\text{ r/min}$$

$$n_{\text{cr}} \times 0,8 = 1\,146 \times 0,8 = 917\text{ r/min} > 600\text{ r/min} \Rightarrow \text{Ok}$$

Speed limit

$$n d_0 = 600 \times 48 = 28\,000 < 160\,000 \Rightarrow \text{Ok}$$

Buckling strength with safety factor = 3

We must consider two critical situations for calculating the buckling strength.

Point (A) (→ **diagram 12**, **page 114**) with maximum application load at end of phase 1 (travel = 1 500 mm) (→ **fig. 36**, **page 116**).

In this configuration, the mounting conditions are fixed/supported with corresponding factor $f_3 = 2$

$$F_c = \frac{34 \times 10^3 \times 2 \times 45,5^4}{1\,719,5^2} = 98\,571\text{ N} > F_1 = 50\,000\text{ N} \Rightarrow \text{Ok}$$

Point (B) (→ **diagram 12**, **page 114**) with lower application load and longer total travel of 2 500 mm at end of phase 2 (→ **fig. 37**, **page 116**)

$$F_c = \frac{34 \times 10^3 \times 2 \times 45,5^4}{2\,719,5^2} = 39\,407\text{ N} > F_2 = 37\,500\text{ N} \Rightarrow \text{Ok}$$

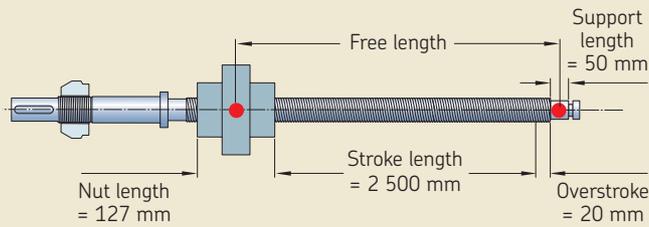

Same case with customer selecting a preloaded roller screw

Should the customer prefer a preloaded roller screw for the application in order to have a stiffer assembly, then the initial selection would be:

PRK 60 × 20R with $C_a = 217\,610\text{ N}$

Now check this screw against all dimensioning parameters.

Fig. 34

$$\text{Free length} = 127/2 + 2\,500 + 20 + 50/2 = 2\,608,50$$

Efficiencies

Theoretical direct efficiency

$$\alpha = \text{Atan} \left(\frac{P_h}{\pi d_0} \right) = 6,05^\circ$$

Taken from the coefficient of friction reference diagram
(→ diagram 1, page 22)

where

$$\mu_{\text{ref}} = 0,013$$

$$\mu_{\text{prac}} = 0,017$$

$$\eta = \frac{1}{1 + \frac{\pi d_0 \mu_{\text{ref}}}{P_h}} = 0,891$$

Theoretical indirect efficiency

$$\eta' = 2 - \frac{1}{\eta} = 0,877$$

Practical direct efficiency

We consider the practical coefficient of friction

$$\mu_{\text{prac}} = 0,017$$

$$\eta = \frac{1}{1 + \frac{\pi d_0 \mu_{\text{prac}}}{P_h}} = 0,862$$

Input torque in a steady state

Phase 1 has the highest application load $F_{\text{max}} = 50\,000\text{ N}$

$$T = \frac{50\,000 \times 20}{2\,000 \pi \times 0,862} = 184,6\text{ Nm}$$

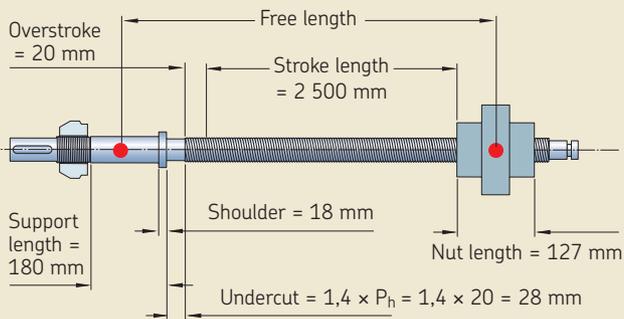

Power requirement in a steady state

Phase 1 has the highest application load $F_{\text{max}} = 50\,000\text{ N}$

Rotational speed is 600 r/min

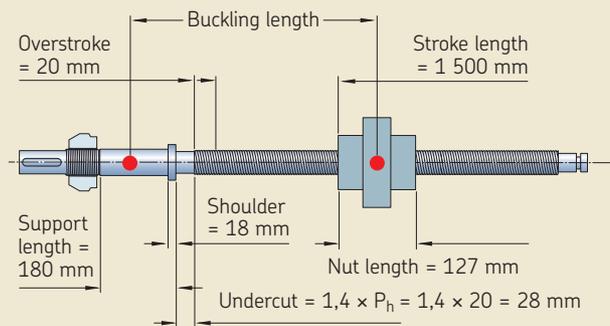

$$P = \frac{50\,000 \times 600 \times 20}{60\,000 \times 0,862} = 11\,600\text{ W}$$

Fig. 35

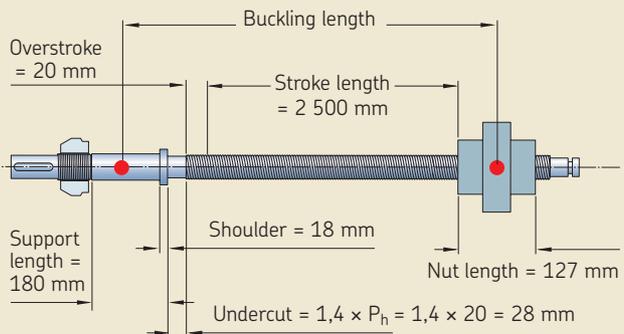

$$\text{Free length} = 127/2 + 2\,500 + 20 + 28 + 18 + 180/2 = 2\,719,50$$

Fig. 36

$$\text{Buckling length} = 127/2 + 1\,500 + 20 + 28 + 18 + 180/2 = 1\,719,50$$

Fig. 37

$$\text{Buckling length} = 127/2 + 2\,500 + 20 + 28 + 18 + 180/2 = 2\,719,50$$

Braking torque

Phase 1 has the highest application load $F_{\max} = 50\,000\text{ N}$

$$T_b = \frac{F P_h \eta'}{2\,000 \pi} = \frac{50\,000 \times 20 \times 0,877}{2\,000 \pi} = 139,6\text{ Nm}$$

Critical speed of screw shaft

Screw type PRK 60 × 20R has a larger nominal diameter and a larger root diameter than screw type SRF 48 × 20R that was already calculated. Therefore, the critical speed will not be a problem for screw size PRK 60 × 20R.

Axial stiffness

In product table on **page 72**, we find that nominal preload

$$F_{pr} = 2\,326\text{ N}$$

First, we confirm that the internal preload is appropriate for the application:

- Minimum application load in phase 4:
 $F_4 = 20\,000\text{ N}$
- F_4 is greater than $2,83 \times 2\,326\text{ N} = 6\,583\text{ N}$

This is to make sure that the nut half that does not carry the load is completely unloaded and does not face marginal loading with risk of sliding. Nominal preload $F_{pr} = 2\,326\text{ N}$ is OK for the application.

Under this nominal preload conditions ($F_{pr} = 2\,326\text{ N}$), the minimum nominal stiffness of the nut is $R_{ng} = 700\text{ N}/\mu\text{m}$ (product table on **page 72**).

Total axial stiffness of the roller screw is:

$$\frac{1}{R_t} = \frac{1}{R_s} + \frac{1}{R_{ng}}$$

At point **(B)** (→ **diagram 12, page 114**), full stroke:

With $d_2 = 57,5\text{ mm}$ for roller screw size PRK 60 × 20R

$$R_s = 165 \frac{57,5^2}{2719,5} = 201\text{ N}/\mu\text{m}$$

$$\frac{1}{R_t} = \frac{1}{201} + \frac{1}{700} \Rightarrow R_t = 156\text{ N/m at full stroke}$$

If we include the axial stiffness of the fixed support bearing FLRBU7, we calculate the total system stiffness:

R support bearing = 1 250 N/μm

$$\frac{1}{R_{\text{total system}}} = \frac{1}{R_s} + \frac{1}{R_{ng}} + \frac{1}{R_{\text{bearing}}} = \frac{1}{201} + \frac{1}{700} + \frac{1}{1\,250}$$

$$\Rightarrow R_{\text{total system}} = 139\text{ N}/\mu\text{m at full stroke}$$

Recommendations for assembly

Handling

Roller screw assemblies are precision components and should be handled with care to avoid damaging shocks, contamination or corrosion. After cleaning, avoid touching the screws with bare hands. Unprotected screws made of standard bearing steel are very sensitive to corrosion.

Storage

Roller screw assemblies should be stored so that they are not exposed to contaminants, vibrations, shocks, humidity or other detrimental conditions.

During shipping, roller screw assemblies are wrapped in heavy gauge plastic bags, which protect them from solid or liquid contaminants. They should remain in the shipping crate and wrapped until they are used.

If they are stored out of the shipping crate, roller screw assemblies must lie on wooden, plastic or aluminum V-shaped blocks and should not be subjected to vibrations. The V-shaped supports should be positioned on the threaded section of the screw shaft, or on the machined ends. The assembly must not be supported on the shelf by the nut body (→ **fig. 38**).

The standard rust inhibitor protects roller screws in their original sleeve for a period of 12 to 18 months. Storage temperature should range between – 10 and +50 °C. For longer storage periods, special packing such as VCI sleeve can be used. For additional information about roller screw storage, please contact your local SKF representative.

Nut disassembly

If possible, do not remove the nut from the shaft, especially for preloaded assemblies. If the nut must be removed from the shaft, i.e. for shaft end machining, check the nut orientation before disassembly.

Identify the type of nut by removing one wiper.

Fig. 41: Planetary roller screw

Fig. 42: Recirculating roller screw

For a recirculating roller screw with a nominal diameter < 16 mm, the nut should never be removed from the screw without using a sleeve (risk of losing the rollers).

For the other recirculating roller screws and for all planetary roller screws, the nut can be removed without any risk. But if the nut is fitted with wipers (components usually are black or white), SKF recommends marking the wipers and their angular position in relation to the nut (→ **fig. 40**) to facilitate the reassembly process.

In order to achieve the proper axial play or preload required by the application, each nut is matched to its shaft. Therefore, special attention must be paid not to mix nuts and shafts during disassembly.

Just changing the orientation of a preloaded nut onto its matched screw shaft will affect the preload torque. Again, special care is required for proper disassembly and reassembly!

With preloaded assemblies (screws types with prefix PRU, PRK, PVU and PVK), do not remove the retaining device used for transportation inside the packaging. The retaining device can be:

- Transportation bolts (usually 3 screws) for the flanged types PRK and PVK
- Retaining strap for the cylindrical types PRU and PVU (→ **fig. 39**). When removing the retaining strap, there is a high risk of dropping the preloading spacers and the key. Therefore, this operation should be performed at the last minute when pressing the nut into its housing

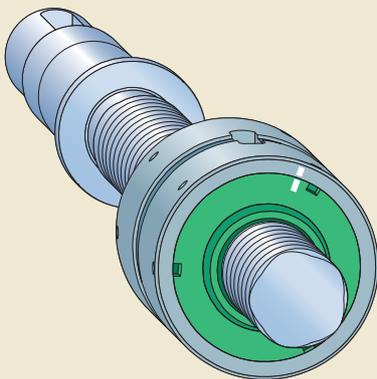

Fig. 41

Planetary roller screw

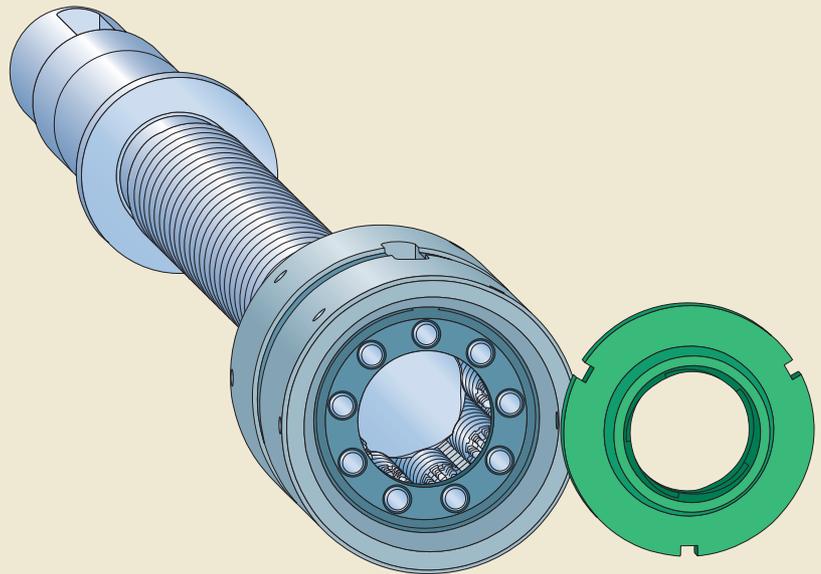

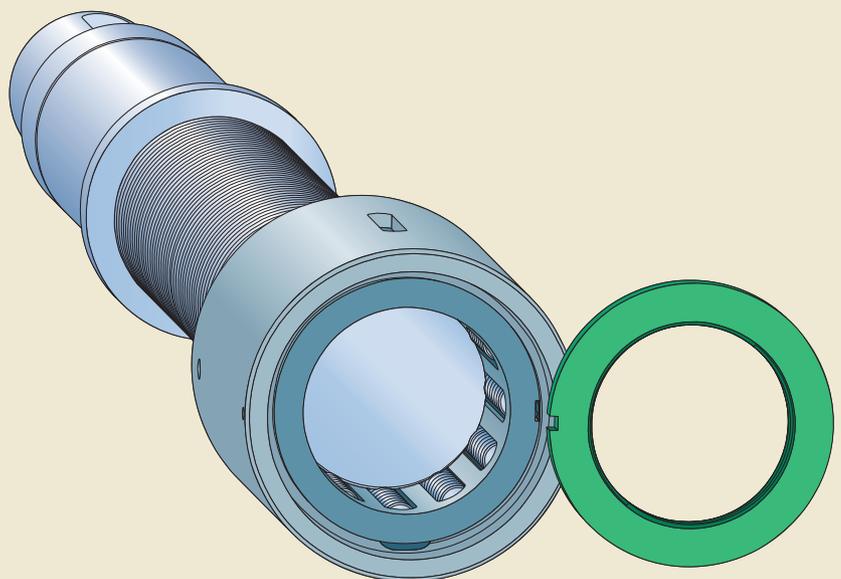

Fig. 42

Recirculating roller screw

Lubrication

The rust inhibitor is not a lubricant. For grease or oil lubrication, please refer to the *lubrication chapter* in this catalogue.

Starting up the screw

After the assembly has been cleaned, fitted and lubricated, allow the nut to make several full strokes at low speed (< 50 r/min) and under light load (not to exceed 5% of the roller screw dynamic load carrying capacity) in order to check the proper positioning of the limit switches or reversing mechanism. Then, normal load and speed can be applied.

Running in period

Non-preloaded roller screws will experience a running in process during the first hours of operation.

SKF recommends injecting half the volume of grease in the nut after running in, to renew the lubricant potentially contaminated by running in particles.

For preloaded roller screws, a running in of 20 000 revolutions is performed before delivery.

Monitoring screw life

At the end of the screw's service life, the following conditions become observable: Fatigue flaking, increase in axial play, deterioration of running behavior, increase in driving torque and increase in operating temperature. Also, lubricant becomes noticeably contaminated. These indicators are important methods of monitoring the condition of a roller screw. Immediate replacement is recommended at the end of the service life in order to avoid any damage to the installation.

Important:

Poor quality or lack of lubricant, abnormal stresses, misalignment and tilting, and operation outside defined specifications will increase operating temperature of the roller screw. Monitoring the operating temperature will help detect any irregularities.

Traceability

Each roller screw shaft and nut are identified by engraving with unique manufacturing order and serial number. Each screw's individual dimensional data, lead precision, axial play, preload torque, etc. are recorded and archived by SKF for a period of 10 years. This period can be enlarged for special applications.

Support bearings assembly

- 1 Check the direction of fitting (position of the flange) before fitting a FLRBU support bearing
- 2 If necessary, heat the FLRBU up to 80 °C with an SKF heater
- 3 Fit the FLRBU on the screw (check that it fits against the surface of the screw flange)
- 4 Prepare the KMT locknut and loosen the KMT locking screws one-quarter of a turn
- 5 Fit the KMT locknut:
 - Tighten to 1,5 times the tightening torque listed in the product table
 - Loosen the nut
 - Retighten the KMT locknut to the torque values listed in the product table and tighten the locking screws
- 6 Check the radial run-out of the machined end and mark the upper point
- 7 If the run-out is out of tolerance, loosen and retighten the radial locking screw which is closest to the previously marked upper point
- 8 Check the radial run-out again
- 9 Check the operation of the support bearing.

Recommendations for bolts used with flanged nuts

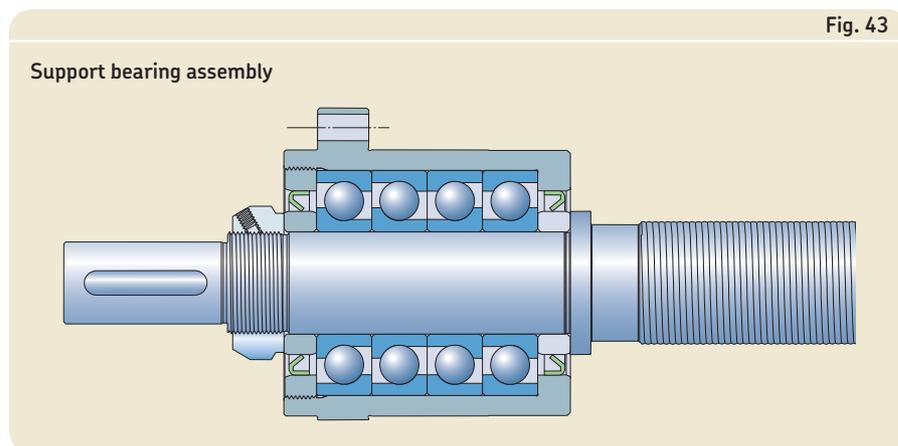

SKF recommends using bolts with steel quality that complies with ISO class 12.9.

Alignment

SKF linear guidance systems should be checked for proper alignment to avoid non-axial loading on the roller screw. If external linear guidance does not meet these requirements, we suggest mounting the roller screw nut on trunnions, or mounting the screw shaft on self-aligning bearings.

For assembly, SKF recommends the following procedure which applies to an assembly with a rotating shaft screw and stationary nut.

The linear guides must be correctly mounted according to recommendations for the selected guidance system.

1 Align the screw shaft with the linear guides

Align the support bearing housings with the guides to obtain parallelism of the screw shaft with respect to the linear guides.

The inclination of the support bearing axis versus the linear guide, in two perpendicular planes, must be less than $1/2\ 000$ rad ($0,03^\circ$), the ideal target being $1/5\ 000$ rad ($0,011^\circ$) (\rightarrow fig. 44).

2 Align the nut housing with the linear guides

Align the roller screw nut housing with the axis of the linear guides to obtain parallelism of the nut axis with the linear guides.

The inclination must be less than $1/2\ 000$ ($0,03^\circ$), the ideal target being $1/5\ 000$ ($0,011^\circ$). These tolerances must be maintained under load (\rightarrow fig. 45).

3 Check the concentricity of the nut housing with the support bearings

SKF recommends checking that the nut housing is not off-centered versus the support bearings of the shaft. Otherwise, the excessive off-centered position of the nut housing would result in unacceptable radial loading on the roller screw. The radial eccentricity in two perpendicular planes must not exceed 0,02 mm between the nut housing bore diameter and the support bearings axis (\rightarrow fig. 46).

4 Check the axial run-out of the nut housing face versus the screw shaft axis (flanged nuts)

SKF recommends checking that the nut housing presents the appropriate perpendicularity to the roller screw axis to avoid the tilting of the screw nut and to avoid uneven loading along the rollers.

The axial run-out of the housing face must be (\rightarrow fig. 47):

- Lower than 0,015 mm for screws with $d_0 \leq 15$ mm
- Lower than 0,02 mm for screws with $15 < d_0 \leq 39$ mm
- Lower than 0,04 mm for screws with $d_0 > 39$ mm.

Electro–mechanical cylinders

The high performance electro–mechanical cylinders incorporate SKF planetary roller screws as the driving force. They are designed for long service life, high accelerations, high force applications and heavy duty cycles.

The modular Electro–Mechanical Cylinder (EMC) offers great design flexibility to cover a wide assortment of industrial applications.

Compact Electro–Mechanical Cylinders (CEMC) deliver a unique combination of design flexibility and powerful actuation within a compact package.

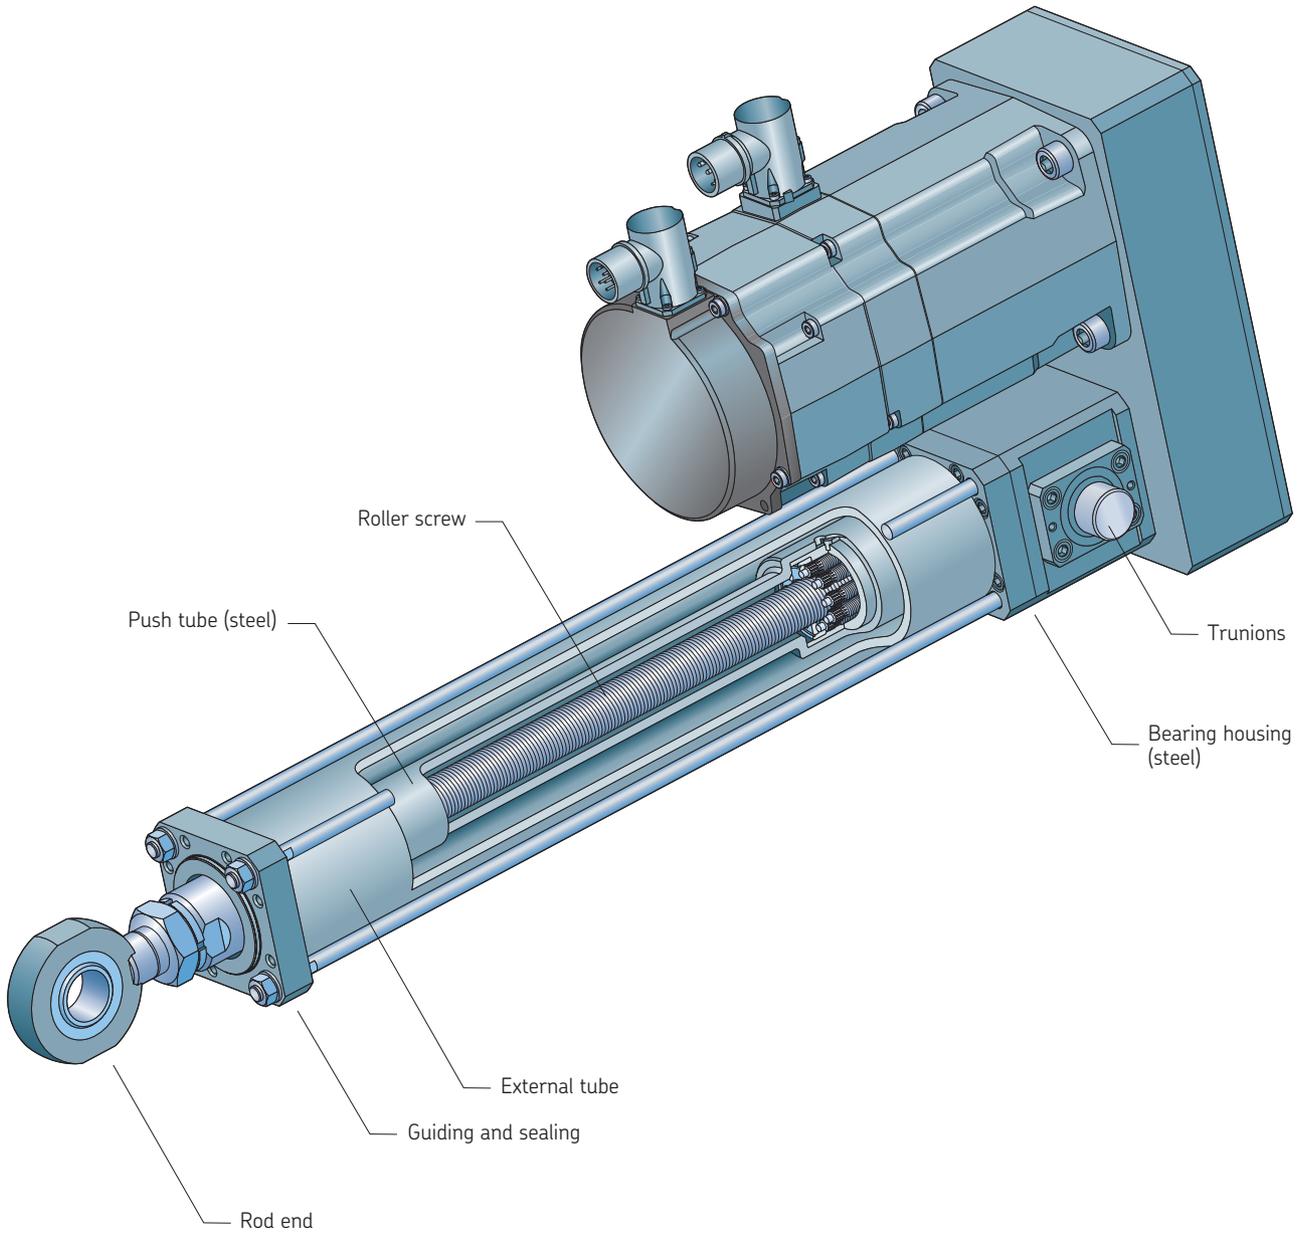

The new Light Electro–Mechanical Cylinders (LEMC) include standard components for greater availability and increased value associated with premium performance.

SKF electro–mechanical cylinders using roller screws expand the limits of linear actuators.

Application examples

- Factory automation
- Automotive assembly lines (welding, riveting, clinching, piercing, etc.)
- Industrial assembly
- Presses, forming processes
- Steel industry
- Test benches
- Simulators, hexapods

Design features	User benefits
Cylinders incorporating high performance planetary roller screws	Cylinders designed for industrial grade applications Suited for high duty cycle with usage rate over 70% Extremely durable and reliable
Roller screws with low axial play	Cylinders with high axial stiffness Increased process repeatability
Planetary roller screws with maximum speed $n_{d_0} = 160\,000$, and acceleration up to $12\,000\text{ rad/s}^2$	High linear speeds up to 1,5 m/s and high accelerations for increased productivity
Premium SKF bearings supporting the rotary components	Same load carrying capacity in both directions
High mechanical efficiency	Low energy consumption and lower total cost of ownership (TCO)
Precise speed control and positioning accuracy	Flexible, functional, controllable
Modular design for the standard EMC assortment, with optional motor integration	Design flexibility to accommodate most custom installations
Efficient sealing	Cleanliness, low maintenance
Push tube guided on bushings fitted into the external housing for optimum rigidity and low vibration levels Internal bumpers Optional anti–rotation function for the push rod	Highly integrated system simplifying customer design and installation
Optional controller	Easy integration

Electro-mechanical cylinders

Modular Electro-Mechanical Cylinders (EMC)

- Modular design with or without motor
- In-line or parallel motor assembly
- Integrated anti-rotation push tube
- Programmable controller
- Internal bumpers
- Limit switches
- Integrated thermo sensor
- Automatic lubrication system
- Maximum load up to 450 kN
- Linear speed up to 1 500 mm/s
- Stroke up to 2 000 mm

Nominal diameter	Screw lead	Nominal force up to	Peak force up to ^{1) 2)}	Linear speed up to ³⁾	Standard stroke ⁴⁾	Dynamic load carrying capacity	Designation
mm	mm	kN		mm/s	mm	kN	–

¹⁾ Peak force to be used during static phases only. During dynamic phases, the peak force must be limited through the motion controller to 80% of the dynamic load carrying capacity

²⁾ Nominal force can be used 100% of the cycle time, at low speed (10% of the rated linear speed)

³⁾ This is the maximum achievable linear speed, to be limited through the motion controller

⁴⁾ For additional information about longer stroke, please contact your local SKF representative

Compact Electro-Mechanical Cylinders (CEMC)

- Integrated brushless servomotor
- High power density
- Low weight for dynamic applications such as robotics
- Compactness
- Fail safe brake
- Programmable controller
- Integrated thermo sensor
- Automatic lubrication system
- Maximum load up to 83 kN
- Linear speed up to 480 mm/s
- Stroke up to 200 mm

Nominal diameter	Design	Screw lead	Nominal force ¹⁾	Peak force ²⁾	Linear speed	Standard stroke	Dynamic load carrying capacity	Designation
mm			kN		mm/s	mm	kN	–
18	Compact	3,75	4,7	10,3	350	145	27	CEMC1804-x2x
24		4	8,7	23,8	300	Up to 200	61	CEMC2404-x2x
		6	5,8	15,9	450	Up to 125	61	CEMC2406-x2x
		4	13,1	26,0	300	Up to 200	61	CEMC2404-x3x
		6	8,7	17,3	450	Up to 125	61	CEMC2406-x3x
24	Ultra-compact	4	14,1	28,2	320	90	61	CEMC2404-Dx2x
		6	9,4	18,8	480	90	61	CEMC2406-Dx2x
30		4	39,5	83,4	266	170	105	CEMC3004-Dx6x
		6	26,3	55,6	400	170	105	CEMC3006-Dx6x

¹⁾ Nominal force can be used 100% of the cycle time, at low speed (1% of the rated linear speed)

²⁾ Peak force represents the maximum force to be applied for short periods of time (1 second max.) at low linear speed and with the selected controller.

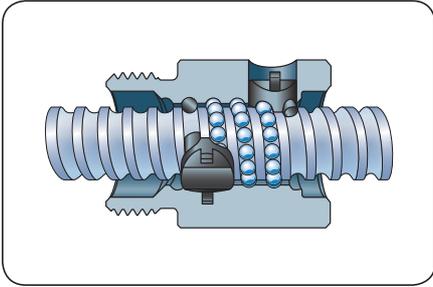

Light Electro–Mechanical Cylinders (LEMC)

- Modular design with or without motor
- In–line or parallel motor assembly
- Integrated anti–rotation push tube
- Programmable controller
- Internal bumpers
- Limit switches
- Maximum load up to 80 kN
- Linear speed up to 1 000 mm/s
- Stroke up to 800 mm

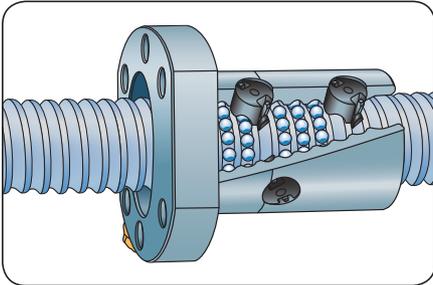

Nominal diameter	Screw lead	Peak force	Linear speed	Standard stroke, by increments of 100 mm	Dynamic load carrying capacity	Designation
mm		kN	mm/s	mm	kN	–
21	5	40	500	100 to 600	51	LEMC2105
21	10	40	1000	100 to 600	54	LEMC2110
30	5	80	440	100 to 800	92	LEMC3005
30	10	80	880	100 to 800	106	LEMC3010

Linear Motion solutions

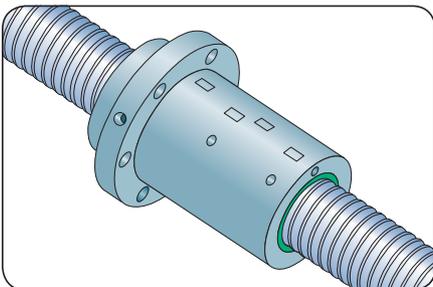

Precision rolled miniature ball screws

- Precision rolled shaft associated with a compact nut design
- Diameter = 6 to 16 mm, lead = 2 to 12,7 mm
- Stainless steel assortment available
- High load carrying capacity within a compact envelope
- Available with axial play or without backlash

Precision rolled ball screws

- Manufactured from SKF high precision rolling process, reaching G5 lead precision defined by ISO standards for ground ball screws
- Diameter = 16 to 63 mm, lead = 5 to 50 mm
- SX value assortment of universal screws ideally suited for transportation and material handling applications
- SN assortment and SND assortment (DIN 69051) of ground nuts for accurate positioning applications, at lower cost than ground ball screws
- SL long lead screws for high linear speed applications
- SLT rotating nuts when lower inertia is required
- Matching assortment of support bearings

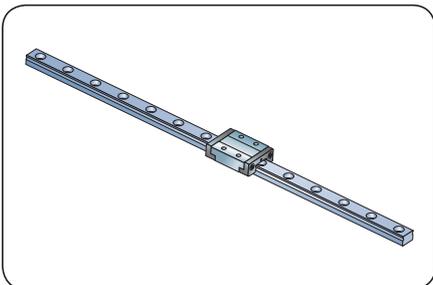

Ground ball screws

- Metric assortment diameter = 16 to 180 mm, lead = 5 to 20 mm
- Inch assortment diameter = 0,5 to 6 in., lead = 0,1 to 1,75 in.
- Cylindrical flanged nuts and DIN nuts
- Available with axial play, without backlash, single nut with internal preload or preloaded double nut
- Matching assortment of support bearings
- Combination of high precision and high stiffness
- Custom solutions on request

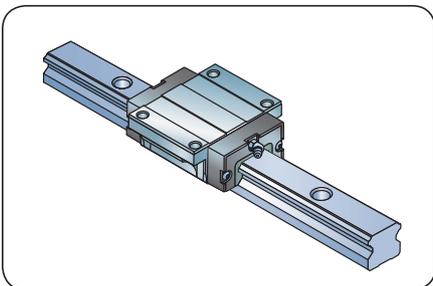

Linear ball bearings

- The cost-efficient guidance system
- Dimensions according to ISO 10285 series 1 and 3, from nominal diameter 5 to 80 mm
- Closed and open designs, rigid and self-aligning designs. Integrated lubricant reservoir. Stainless steel option
- Wide assortment of accessories stocked at SKF such as linear ball bearing housings, ground shafts, shaft supports and shaft blocks
- Load carrying capacity and sealing performance optimized for maximum service life

Miniature profile rail guides

- The compact high precision profile rail guide for space saving and reduced machine weight
- Sizes 7 to 15 with interchangeability to DIN 645-2
- Standard width rail and larger rail for increased moment carrying capacity
- High precision ground raceways and carriages with two rows of balls offering high load carrying capacity in all four radial directions
- Stainless steel components and factory pre-lubrication for high reliability

Profile rail guides

- The ideal guidance system in combination with driving by precision rolled ball screws in most machinery
- Rail sizes 15 to 45 with interchangeability to DIN 645-1 and upcoming ISO 12090-1. Variety of carriage types manufactured according to industry standards
- High precision profile rail guide with precision ground raceways and carriages, available with various classes of precision and preload
- 4 bearing raceways with X-arrangement providing equal load carrying capacity in all four radial directions, and ability to resist over-turning moments
- Accessories stocked at SKF such as low friction seals, scrapper seals, bellows, lubrication systems, etc.
- Solutions adapted to various types of applications and requirements

Designation system

Complete roller screw assembly		SRF	30 × 5R	425/590	G5	L	Z	WPR
Nut type								
SRC	Planetary roller screw, axial play, cylindrical nut							
BRC	Planetary roller screw, without backlash, cylindrical nut							
SRF	Planetary roller screw, axial play, centered flange							
BRF	Planetary roller screw, without backlash, centered flange							
SRP	Planetary roller screw, axial play, off-centered flange							
BRP	Planetary roller screw, without backlash, off-centered flange							
PRU	Planetary roller screw, preload with split nut, cylindrical nut							
PRK	Planetary roller screw, preload with split nut, centered flange							
HRC	Ultra Power planetary roller screw, cylindrical nut							
HRF	Ultra Power planetary roller screw, centered flange							
HRP	Ultra Power planetary roller screw, off-centered flange							
ISR	Inverted planetary roller screw, axial play							
IBR	Inverted planetary roller screw, without backlash							
SRR	Planetary roller screw, rotating nut, axial play							
BRR	Planetary roller screw, rotating nut, without backlash							
SVC	Recirculating roller screw, axial play, cylindrical nut							
BVC	Recirculating roller screw, without backlash, cylindrical nut							
SVF	Recirculating roller screw, axial play, centered flange							
BVF	Recirculating roller screw, without backlash, centered flange							
PVU	Recirculating roller screw, preload with split nut, cylindrical nut							
PVK	Recirculating roller screw, preload with split nut, off-centered flange							
Nominal diameter × lead [mm]								
Hand								
R	Right							
L	Left (on request)							
Threaded length/Total length [mm]								
Lead precision								
G5	Standard lead precision							
G3	Lead precision on request							
G1	Lead precision on request							
Flanged nut orientation								
S	Nut ground outer diameter D (g6) oriented towards shorter machined end of shaft							
L	Nut ground outer diameter D (g6) oriented towards longer machined end of shaft							
-	In case of identical machined ends, and for cylindrical nuts							
Shaft machined end								
Z	According to customer drawing							
Wipers								
WPR	With wipers							
NOWPR	Without wipers							
NORCS	Nut design without wipers recesses (for special SR nut types only)
